* Received June 8, 1937.

the patients afterwards deny having any memory of the operation.

Many of my cases have been dealt with in the nursing home of Sister E. E. Hughes, and Sister A. Bryant, formerly staff-nurse to the eye department of St. Bartholomew's Hospital. They have been impressed by the absence of post-operative mental and other distress in cases operated on under "surgical narcosis"—an opinion more convincing when expressed by the nursing staff than by a surgeon who visits the patients only briefly.

Modified Technique of Operation

The patient being soundly asleep, the conjunctiva is incised along WX (Fig. 3) and is retracted to GH. The steadying suture, R, is then inserted in the superior rectus tendon. With a "broad needle" (N, Fig. 3) I then pierce a small tunnel, T, in the surface of the "cleaned" sclera. Perforation of the sclera has been done daily for decades in inserting the stitches in operations for squint. This tunnel, instead of being horizontal, may be vertical (T^1, Fig 4), a special broad needle (bent on the flat at K) being used. In the drawings here reproduced the tunnel has been drawn arbitrarily either vertical or horizontal. The relative merits of each cannot be described here; on the whole the vertical (Fig. 4) is preferable.

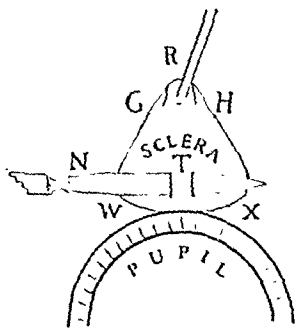

FIG. 3.

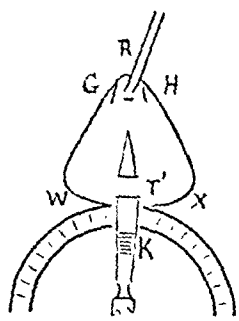

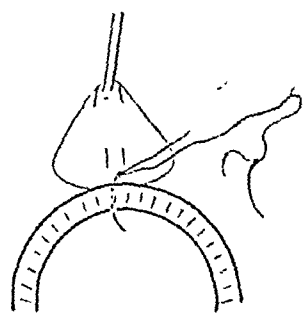

FIG. 4.

FIG. 5.

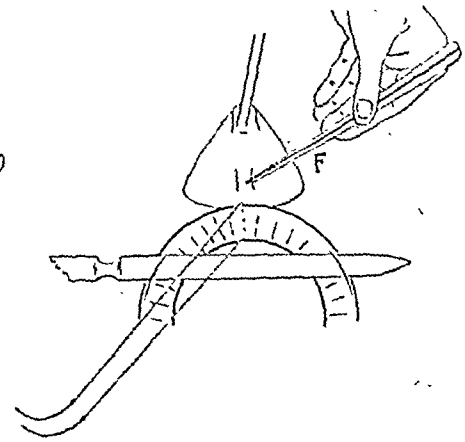

FIG. 6.

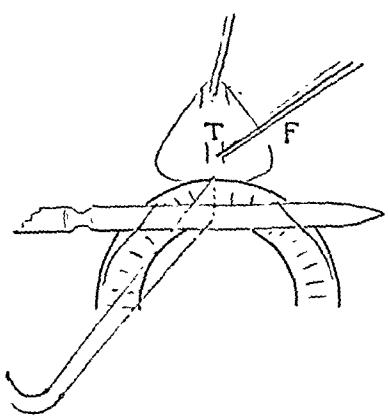

FIG. 7.

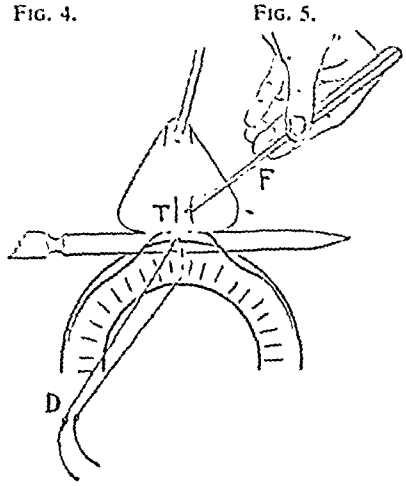

FIG. 8.

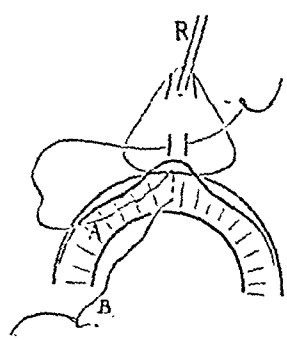

FIG. 9.

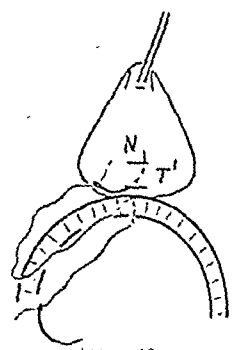

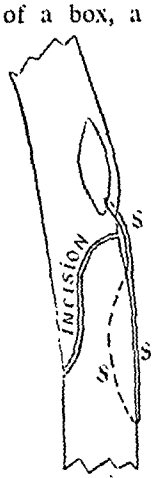

FIG. 10.

One of two fine needles (Fig. 5) on a piece of Wiess's finest black silk is then inserted through the middle layers of the cornea, without penetrating to the interior of the eye. The precise manner of inserting this corneal suture in relation to the tunnel, T, depends on the way chosen to tie it at the end of the operation. The assistant then holds the steadying superior rectus stitch (R, Fig. 3) with one hand and this fine corneal stitch with the other. In making the incision to open the eye the operator secures an absolute yet most delicately variable control of the eye—from what is mechanically the correct point of application—by gripping the edge of the cover of the tunnel, T, with a pair of fine-pointed forceps (F, Figs. 6, 7, 8).

The knife, which has been dipped in hot vaseline, is passed slowly upwards behind the corneal stitch (Figs. 6, 7, 8) and, after a deliberate pause to select the site, is slowly brought out between this stitch (D, Fig. 7) and the tunnel, T. One end of the corneal suture is then threaded through the tunnel (Fig. 9). Alternatively, the needle (N, Fig. 10) can have been placed in the tunnel before the incision is made, after which it is drawn completely through. (If it is drawn right through before this there is risk of cutting the stitch as the knife emerges.) By pulling on the parts A and B of this thread (Fig. 9) the incised upper part of the cornea is lifted up like the lid of a box, a piece of the lens capsule is removed with capsule forceps, and the cataractous nucleus is tilted forward and upward by the lightest of pressure on the lower part of the cornea and is then picked out on the point of a cystitome.

S: STITCH
FIG. 11.

The dilated iris is not touched throughout the operation; no iridectomy is needed. The fine suture is then pulled fully through the tunnel and tied, after which it is passed through the conjunctiva and tied again. Fig. 9, in which the conjunctiva is omitted, shows sectionally how the suture does not enter the interior of the eye. Drops of atropine, 1 per cent., and argyrol, 15 per cent., are finally instilled.

The patient sleeps on for seven to fourteen hours and sits up in bed the next day, rested and free from pain, and usually can sit out of bed on the third day instead of the customary seventh. In trephining for glaucoma I put the patient to sleep in a

similar way. The superior rectus stitch gives adequate steadying of the globe in trephining, and abolishes any need of the patient's co-operation.

Conclusion

I have given the procedures mentioned here a long and detailed trial. They will be described more fully in a publication I have in preparation. I think that eventually the custom of patients walking into an operating theatre and consciously co-operating in the performance of an operation on their own eye may come to be regarded as anomalous. Apart from the absence of discomfort and distress in the days following the operation, and the benefit to the patient of being asleep during it, the advantage it affords to the operator is such that I believe no operator who had accustomed himself to the method I have described would care to resume cataract-extraction, or glaucoma-trephining, on patients when they were not thus asleep. Nervous patients can be kept asleep for still longer by the administration of more hypnotics later. The eye is the only transparent part of the surface of the body. After an operation for cataract, expert examination can at any time during the rest of the patient's life provide an accurate estimate of the competence of the technique employed by any operator. It follows that theoretical objections to innovations can always be met with the proposal that all cases be submitted after operation to impartial expert examination.

Clinical Memoranda

Bilateral Spontaneous Pneumothorax

In view of the article by Dr. R. A. Young (1936) in the *British Medical Journal*, and a further communication by Herbert L. Settle (1936), it is hoped that the following case will be of interest. Although I did not see this patient the full notes were passed to me for perusal, and from them the following extract was made.

At Jerusalem Sergeant B, aged 34, a quiet, temperate, and apparently healthy young man, rose from his bed before réveillé on November 11, 1936, and complained to his comrades of a pain "below the chest." He then went for a short walk, and on his return said he felt better. He ate a usual breakfast, but at 8.30 a.m. he went back to the sergeants' mess and ordered a lemonade, which he drank quickly, saying afterwards, "That's better." Later in the morning, while in the orderly room, he suddenly fell face forward to the ground. He was removed to hospital immediately, but on examination was found to be dead. Prior to this catastrophe there had been no undue strain from laughing, coughing, sneezing, shouting orders, or from exercise such as running or mounting stairs. There was no history of injury to the chest wall. At the post-mortem examination both lungs were found to be completely collapsed. The lungs were of normal texture, and there was no macroscopic evidence of tuberculous, neoplastic, or other disease. The pleural surfaces were normal in appearance over the whole of the lungs and chest wall. The pleural cavities contained no exudate. There was no evidence of an opening on the lung surfaces when water from a tap was forced through the main bronchi. The heart was in diastole, with well-developed and normal muscle. In the pericardial cavity there was no excess of fluid and no sign of inflammation. The brain and abdominal viscera appeared healthy and free from tuberculosis. The cause of this sergeant's sudden decease was considered to be due to spontaneous bilateral pneumothorax.

This case appears, therefore, to belong to the class described by Dr. Young in his paper as pneumothorax in the apparently healthy, or pneumothorax simplex.

From the history it is most probable that it was the occurrence of a sudden pneumothorax on one side which caused him to wake up before réveillé complaining of "pain below the chest," by which he meant, presumably, the upper abdomen. Settle's patient, too, complained of pain in the same region. That the soldier did not feel quite comfortable from that time until 8.30 a.m. is evidenced by his return to the sergeants' mess for a drink; and, from what he said, the fizz of the lemonade temporarily eased his discomfort. It is further presumed that somewhat later, when he was in the orderly room, pneumothorax occurred on the other side, thus causing the inevitable and immediately fatal result.

My thanks are due to Colonel G. H. Richard, Deputy Director of Medical Services, British Forces in Egypt, and to Colonel R. W. D. Leslie, O.B.E., late Deputy Director of Medical Services, Palestine, for permission to submit these notes for publication.

R. PRIEST, M.D., F.R.C.P., K.H.P.,
Brevet Colonel R.A.M.C.: late Consulting Physician, Palestine and Egypt Forces.

Case of Herpes Zoster with Facial Paralysis

The association of common facial palsy with herpes zoster of the neck is rare, and is of interest in view of the controversy regarding the causative organism and its mode of transmission in the latter disease.

The patient, a rather anaemic male aged 62, complained on April 8 of pain in the left occipital region, below the ear, and over the sternomastoid area of the left side of the neck. The pain continued for three days, and was described as being like a neuralgia. He had been employed as a night watchman on a road-building scheme, being exposed for hours at a stretch to cold winds. Three days later an erythema appeared on the left side of the neck, and on examination some hours after I found a typical vesicular rash of herpes zoster over the sternomastoid region on the left side, together with some adenitis in the posterior triangle. The cutaneous area affected by the vesicles suggested involvement of the second cervical nerve.

On the following morning I saw him again. He was now tender below the left ramus of the jaw, and complained of his left eye "running." Examination of the face showed evidence of a left-sided common facial palsy with the mouth drawn to the right side, inability to close the left eye, epiphora, and escape of fluid after drinking from the left corner of the mouth. No other cranial nerve was found to be affected. His temperature was 99.2° F., and pulse 88. With warmth and rest in bed the facial palsy soon improved, and, with the herpes, had disappeared in a fortnight.

The organism responsible for herpes zoster is a filterable virus, the infection passing outwards along the sensory nerve from the corresponding posterior root ganglion. Degenerative changes may spread upwards into the posterior columns of the cord and downwards along the peripheral nerves. On rare occasions the infection has spread horizontally in the spinal cord from the posterior to the anterior horn, resulting in a motor paralysis. The temporary paralysis of the seventh cranial nerve may be explained in this way, the only other solution occurring to me being that the two simultaneous conditions of palsy and herpes were separate entities, the cold winds acting as a common exciting factor.

Reviews

ENDOCRINOLOGY

The Endocrines in Theory and Practice. Articles republished from the *British Medical Journal.* (Pp. 278. 9s. net.) London: H. K. Lewis and Co. 1937.

It was a wise move on the part of the *British Medical Journal* to invite a series of articles on endocrinology and to republish them in book form. One's first impulse is to congratulate the Editor on planning the series and choosing the contributors, for the success of the enterprise is largely due to his generalship. It is curious that good endocrinologists have written bad books when left to their own devices and that the two best books on endocrinology have been produced when they have been led in editorial chains. Both these books were published by medical associations because important advances have been made and difficulty is experienced by the ordinary medical man in separating the wheat from the tares so assiduously sown by those whose interest in endocrinology is commercial. The American Medical Association's symposium on *Glandular Physiology and Therapy* (1935) was an amazing achievement, which it is fair to say no other country in the world could have duplicated, and it at once became the research student's bible, but it is rather heavy going for the ordinary practitioner. The *British Medical Journal's* book on the *Endocrines in Theory and Practice* is built on simpler lines and fulfils the task of bridging the gap between theory and practice. For, as Sir Humphry Rolleston indicates in his chapter on the history of endocrinology (curiously placed at the end of the volume), the output of scientific investigation has been enormous, and practical application of this new knowledge has not had time to keep abreast.

Much of the work of the past has been discredited because the extracts used were utterly powerless, excessively weak, badly contaminated, or given in vehicles or channels through which they were imperfectly absorbed or too rapidly excreted. Effects differ in different species, and there is therefore an immense field for clinical research, in which the only, but at the same time the indispensable, apparatus is a critical outlook and knowledge of the pitfalls of therapeutic trials in man. Powerful extracts are now available from almost all the endocrine glands, and in many cases the chemical constitution and formulae are known. Wherever possible, as suggested by Professor E. C. Dodds, dosage should be expressed in milligrammes of crystalline material, for the units derived from small animals such as the mouse and the rat need multiplying to astronomical figures to produce effects in man, and the practitioner, unconsciously influenced by memories of units of antitoxin and insulin, may be afraid to give adequate amounts. This may be one reason why the harvest of the new knowledge has so far been disappointing, and in the field of the sex hormones we can point as yet to little more than the relief of menopausal symptoms by oestrin and the acceleration of imperfect migration of the testes by gonadotropic hormone from the pituitary or the urine of pregnancy.

Many readers distrust popular reviews as they so often degenerate to the level of favourite prescriptions and unjustified generalizations. The present volume is free from such faults: the physiology of the glands is clearly described and therapeutic advice is based on experiment. The pituitary gland is described first, as befits its dominant role, and then follow accounts of the thyroid, adrenals, gonads, thymus, pineal, and parathyroid glands, with separate chapters on menstruation, pregnancy, and the menopause. It is invidious to cite names where all are good, but special mention must be made of the introductory chapter in which Sir W. Langdon-Brown discusses the present position of endocrinology. He points out how the endocrine glands have come under the control of the diencephalo-pituitary system and are linked with the central nervous system and the autonomic. The hormones themselves fall into two groups: the first, of complex chemistry, are formed by the pituitary gland, which uses them to stimulate or inhibit the secretion of the second, chemically simpler grade, by the other endocrine glands. The latter have affinities with the substances by which nervous impulses are transmitted, with the stimulants to the organization of the embryo, and with certain carcinogenic chemicals. We can now clearly see a future in which the halting language of infant science is discarded and we no longer speak of vitamins, hormones, or vagus-stuff, but of ascorbic acid, thyroxin, acetylcholine, and other equally well-defined substances.

L. J. WITTS.

THE PROBLEM OF DRUG ADDICTION

Drug Addiction. By E. W. Adams, O.B.E., M.D. (Pp. 174; 8s. 6d. net.) London: Oxford University Press, Humphrey Milford. 1937.

Drug addiction is a many-sided problem, and it is rare to find the subject dealt with as a whole, because few writers have knowledge of all its aspects, political, social, medical, and pharmacological. Dr. E. W. Adams has, however, very exceptional knowledge and experience, because not only is he a pharmacologist, but he has also had under the Ministry of Health full acquaintance with the administrative features of the problem. Hence his book, though short, deals with all the aspects indicated. With regard to the range of drugs discussed it may be mentioned that the author does not touch on alcoholism and devotes his attention especially to the "white drug"—namely, morphine, heroin, and cocaine. So far as these are concerned he gives a very full account of the world problem as it exists to-day. The only aspect he leaves alone is the commercial one. The manner in which the drug industry has catered for the vices of mankind is a lurid story, which probably has been omitted for reasons of prudence.

Dr. Adams gives a brief outline of the history of addiction to opium, to cocaine, and to morphine and its derivatives. The chapter on epidemiology is very clear and interesting. In this respect Great Britain occupies an exceptional position, since the number of addicts is estimated at less than 1,000, whereas the estimated figures for the U.S.A. and Canada are 100,000 and 8,000 respectively. One of the primary facts that British writers must remember in discussing the importance of drug addiction is that our country is exceptionally lucky. Aetiology is fully discussed; the association between crime and addiction is very clear in the United States, and the problem is whether addiction should be looked upon as the cause or the consequence of criminal tendencies. Dr. Adams suggests that there are at least three classes of addicts: accidental, natural, and criminal. The first class comprises normal persons who have accidentally become habituated to drugs. The second class are people of inadequate personality who seek in drugs an escape from reality. The third class are the fundamentally vicious type.

The pharmacological problems of the mechanism by which tolerance and addiction to drugs are established are dealt with fully, and so also are the methods of treatment. It may be said that, in spite of the intensive research that has been carried out during the last decade, there is as yet no satisfactory explanation of the pharmacological basis of drug tolerance and addiction. Hence methods of treatment are still empirical. With regard to therapeutic measures the author emphasizes the fact that it is useless to break addiction unless this is followed by some process of rehabilitation, since otherwise relapse nearly always occurs. Drug addiction, as we have said, presents a protean problem of which it is extraordinarily difficult to give a brief and yet comprehensive survey. Dr. Adams must be congratulated on having produced a well-balanced and readable account of this intricate subject.

A MEDICO-LEGAL VOCABULARY

A Dictionary of Medico-Legal Terms. For Criminal Lawyers and Police Officers. By Albert Crew and K. W. Aylwin Gibson, M.R.C.S., L.R.C.P. (Pp. 80. 5s. net.) London: Sir Isaac Pitman and Sons, Ltd. 1937.

One of the barriers which prevent the medical and legal professions from understanding one another is language. Medical men think in a rich and complicated technicology which means little or nothing to laymen. They are so used to this dialect that they forget that there is anything extraordinary about it. Experienced medical witnesses know how to make themselves clear to judges, counsel, and jury, but witnesses of less experience cannot escape from the bounds of their professional vocabulary, either in giving oral evidence or in writing reports. Moreover, medicine permeates the practice of law over a much wider field than most medical practitioners realize. A solicitor or barrister who handles personal injury cases, workmen's compensation cases, or probate actions, to mention only a few, often has to understand medical reports or proofs. This small dictionary will fill a great need, for it contains most of the ordinary medical terms which are met with, at any rate in criminal practice, and also most legal terms the meaning of which ought to be known by medical witnesses. Mr. Crew is a prominent members of the Criminal Bar and Dr. Gibson has long experience of the law; between them they have compiled an accurate and clearly intelligible series of definitions. The preface contains a caution to medical witnesses to use intelligible language, and the authors quote the classic instance in which a witness defined a black eye in terms of contusion, ecchymosis, and abrasion. The reviewer was recently taken to task for using this very instance, but maintains that it is still the best example of the misuse of technical jargon. The author's support for this view is reassuring.

LECTURES ON FEVERS

Maladies Infectieuses (Deuxieme Serie). Leçons Cliniques Professees a l'Hôpital Claude-Bernard. By A. Lemierre. (Pp. 310. 55 fr.) Paris: Masson et Cie. 1937.

In this second series of clinical lectures on infectious diseases—the first was reviewed in these columns two years ago (1935, 2, 15)—Professor Lemierre deals with a number of cases, most of which found their way into the Claude-Bernard Hospital, a fever hospital in Paris. Although every case receives exhaustive attention in respect of aetiology, clinical symptoms, pathology, diagnosis, and treatment, yet each has been primarily selected for some special reason: thus two cases of Hodgkin's disease because they were mistaken for undulant fever; a case of Weil's disease because the jaundice was wanting; several cases of ulcerative pharyngo-stomatitis (misdiagnosed as diphtheria) on account of their causes (the administration of salts of mercury and bismuth in unsuitable patients, the eruption of teeth, and leukaemia). One case of kala-azar and a few of malaria are introduced, partly as a warning that these diseases are indigenous in certain districts of France, partly because of difficulties of diagnosis. A particularly interesting lecture is that on a case of a haemorrhagic exanthem due to novarsenobenzol, suspected of being haemorrhagic small-pox. The rashes caused by this drug may simulate those of certain of the infectious diseases, and Professor Lemierre discusses Milian's hypothesis of biotropism, according to which certain drugs have the power of bringing into action any micro-organisms which happen to be latent in the body, so that these drug rashes are really evidence of attacks of such diseases as scarlet fever and measles. This hypothesis, however, has not met with general acceptance. The remaining lectures are devoted chiefly to septicaemia due to organisms rarely found in that condition, and to unusual cases of erysipelas.

This volume affords highly interesting and instructive reading, valuable both to the specialist and to the general practitioner

CHRONIC RESPIRATORY DISEASES

The Diagnosis and Treatment of Chronic Diseases of the Respiratory Tract, with Especial Reference to the Lesions of the Trachea, Bronchi, Lungs, Pleura, and Diaphragm. By Elmer H. Funk, M.D. Revised by Burgess Gordon, M.D. (Pp. 618; 182 figures. 40s. net.) New York and London: H. Milford, Oxford University Press. 1936.

This book has been produced on a lavish scale, and is therefore published at a price which puts it out of the reach of many for whom it is intended—in this country at all events. The actual contents do not justify either the lavishness or the price. There is evidence of acute clinical observation, and there is a due appreciation of the relative importance of various factors in diagnosis and treatment; but the style is heavy, and the arrangement of the subject-matter is confusing and shows lack of proportion. Indeed at times the book suggests a collection of essays rather than a textbook. Thus special chapters are devoted to curiosities like fibrinous bronchitis, broncholithiasis, chylothorax, and hernia of the lung, subjects of no practical importance to the general practitioner, for whom presumably the book was written, since minute details of procedures like strapping the chest are given, and the use of expectorants and similar drugs is fully discussed. The summary handling of some subjects—for instance, twenty lines are devoted to the pathogenesis of pulmonary tuberculosis—is not merely uninformative but may be misleading. Several inaccuracies and omissions can be pointed out. Phrenic avulsion is discussed in four pages, but the "crush" operation is not mentioned; atelectasis and collapse are considered throughout as synonymous; and we cannot agree that congenital bronchiectasis is rare and of interest only to pathologists, or that only 5 per cent. can benefit by supplementing pneumothorax with pneumolysis. The author's close association with bronchoscopic clinics is shown by constant reference to the value of this diagnostic and therapeutic measure. In fact in discussing the lipiodol investigation of the lungs no details of the other methods of introducing lipiodol are given, such as the cricothyroid and transglottic routes—exclusively employed here. On the other hand several subjects, often ignored elsewhere, are discussed in this book in a practical and concise manner—for instance, heliotherapy in pulmonary

tuberculosis. Many useful skiagrams are reproduced in the text.

The scope of the book is not broad enough for the specialist in chest diseases; the points we have indicated above show that it is too wide for the general practitioner.

FLORENCE NIGHTINGALE

Florence Nightingale. The Woman and the Legend. By Margaret Goldsmith. (Pp. 320. 15s. net.) London: Hodder and Stoughton. 1937

Here we have a further contribution to the literature on this remarkable Victorian, of whom thirteen other biographies are cited in the list appended to the present volume. The author gives a balanced account of Miss Nightingale's life and work, successfully resisting the temptation to be carried away by admiration and sympathy for her heroine, and giving adequate, though not undue, attention to certain defects in her character. Naturally there is much in this book to interest medical readers. The appalling conditions existing in the military hospital at Scutari, where Miss Nightingale arrived a few days after the Battle of Balaclava, are described in some detail. The unfortunate patients, many of whom were suffering from cholera and dysentery, were fed entirely upon meat; their quarters were overcrowded, ill ventilated, and filthy; the sanitary arrangements were at one time so inadequate that only twenty chamber pots were available for the use of two thousand men. The story of how Florence Nightingale, hampered at every turn by the intricacies of red tape and stubbornly opposed by the majority of the Army medical authorities, produced order out of chaos, ameliorated the lot of the wounded, and within six months reduced the death rate at the hospital by nearly 50 per cent., is an epic of determined perseverance and a triumph of organization.

In the concluding chapters the author does not unravel as clearly as one could wish all the threads of Miss Nightingale's later work. Apart from this criticism her book may be commended as an excellent biography of one whose life exerted an immense influence on hospital management and the nursing profession.

Notes on Books

The monograph by Dr. MARCEL GERVOIS, entitled *Le Bacille de Type Bovin dans la Tuberculose Humaine* (Lille, L. Daniel) consists entirely of a review of existing knowledge. The author is appalled by the general ignorance and apathy hitherto manifested in so many countries in relation to the problem of tuberculosis of bovine origin. At a time when there seems at last to be some evidence of awakening of the public conscience towards the hygiene of milk, he thinks it opportune to present a summary of the evidence on which our case against the bovine tubercle bacillus, and particularly milk-borne tuberculosis, is based. The monograph itself consists largely of tables reviewing the findings of different workers in different countries during the past fifty years. Some idea of the work involved may be gathered from the fact that the results of no fewer than 17,045 examinations of tuberculous material for determining the type of infecting bacillus have been collected, and that the table of figures giving the frequency of tubercle bacilli in milk covers eighteen pages. Even those who are well acquainted with the subject material will be astonished at the massiveness of the documentation which the author has been able to build up against the bovine tubercle bacillus. His general conclusion that pasteurization of milk affords the only immediate practical and efficacious method of combating tuberculosis of bovine origin is inescapable.

The realization that despite the great reduction in the infantile mortality rate in the last fifty years the neonatal death rate has not followed this downward path has led to an increased interest in the whole problem of the very young infant. In *Diseases of the Newborn* (H. Milford, Oxford Press, 27s. 6d.) Dr. ABRAHAM TOW has performed a valuable service by not only collecting the latest views in the literature, but also adding observation of his own, a particularly useful feature when he is discussing controversial matter. The subject is well covered from the preliminary considerations of physiological principles and feeding to more detailed discussions of the disorders commonly met with. The section on the premature infant is particularly good in its presentation of modern views, though it may be noted that the incubator is now being discarded in many centres. The chapter on birth injuries is somewhat uneven, and there is no indication that intracranial disorders (for example, cerebral oedema) other than actual haemorrhage may occur: Cruickshank's classical monograph on this has apparently not been consulted. This, however, is the only serious omission found, and the book may be confidently recommended to all those concerned in the care of the newborn infant.

Biological Time, by LECOMTE DU NOÜY, is a short volume in which this problem is dealt with in an original manner. The author, who is a distinguished physical chemist, assisted Dr. Alexis Carrel in his work during the war in Hospital 21 at Compiègne. The systematic study of the healing of wounds which they carried through showed that the process proceeded at a rate which could be expressed by mathematical formulae. They also found that the rate of healing was a function of the age of the patient. Later experiments with tissue cultures showed that, when these were grown in serum, the rate of division was a function of the age of the animal from which the serum was taken. From these and similar experiments the author deduces the idea of a biological time which alters with age. Such a conception is of course familiar to biologists in general and clinicians in particular. One of the most obvious facts in clinical medicine is that a diseased infant changes its condition far more rapidly than does an adult. From these familiar facts the author makes a variety of interesting philosophical deductions concerning the nature of time. His book is published by Methuen and Co. at 7s. 6d.

The Proceedings of the second International Medical Week in Switzerland have now been published. This congress was held at Lucerne in the first week in September last year. The majority of the papers read then appear in German, but some are in French, including the opening speech by Dr. H. Carriere, director of the public health service in Berne. The main subjects under discussion related to diseases of childhood, hormones and vitamins, and affections of the circulation and respiration, but various papers on other medical subjects are incorporated in this report, which is produced by the *Journal Suisse de Médecine* and published by Benno Schwabe and Co., Basle.

Dr. JAIME MENDOZA'S *Notes of a Doctor* (Sucre, Escuela Tifografica Salesiana) are divided into two unequal parts. The first and larger part, entitled "Essays," deals mainly with the medical aspects of Bolivia, especially as regards the incidence of tuberculosis, congenital syphilis, and malaria in that country; while the second part is devoted to psychiatry, the history of the Medical Institute at Sucre, founded in 1892, and infant welfare.

Dr. ROBERT HUTCHISON'S wise little book on the *Elements of Medical Treatment*, which originally appeared rather more than ten years ago, has now come out in a third edition, and the author has made some minor changes and additions to bring his material abreast of present practice. The publishers are John Wright and Sons; the price is 5s.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 14 1937

THE WORK OF THE MINISTRY OF HEALTH

The Ministry of Health is not merely concerned with health, a fact which has to be noted in relation to the financial statistics contained in its annual report[1] and widely quoted. Much local government activity not directly affecting the health of the people comes under its purview, especially if capital expenditure is involved, and the block grant it administers covers many services. It is therefore difficult to discover what the country spends on the preservation and restoration of health out of moneys raised by central and local taxation. In 1936–7 central departmental administration cost £2,219,985. On national health insurance £34,200,000 was expended out of a revenue totalling £37,400,000, which contained an Exchequer grant of £5,925,000. The outlay included £6,868,900 paid to insurance practitioners in capitation fees, £204,000 for mileage, £190,000 for medicines and appliances supplied or dispensed by them, and sundry smaller sums for medical purposes. For objects, therefore, which are directly intended to promote health, rather more than thirty-six millions were spent through central channels in addition to grants to local authorities. On what is called public health local authorities disbursed £44,200,000 net (which included expenditure falling on Government grants), but this covered items like baths, washhouses, parks, and public conveniences, which do not fall within the province of public health unless the term is used in a very broad sense; while the cost of the school medical service and the very large organization for the care of the sick under the Poor Law are not separately distinguished. The treatment of mental disease and deficiency cost about £11,800,000, and housing £16,800,000 net, towards which grants amounting to more than fourteen millions were received from the Ministry. If the very substantial proportion of public assistance expenditure (totalling just short of £40,000,000) attributable to domiciliary and institutional care of the sick were added the local cost of sickness and the preservation of health might be estimated at about £100,000,000.

[1] Ministry of Health, Eighteenth Annual Report, 1936–7. H.M. Stationery Office, Cmd. 5516. 1937. (5s.)

Figures of this order, while falling far short of the whole cost of what are called the social services, naturally impel the Minister to prove that they are balanced by returns in the form of a healthier and fuller life for the people. The standardized death rate has fallen from 13.0 to 9.2 per 1,000 since the Ministry was constituted in 1919, the infant mortality per 1,000 live births from 89 to 59. Even the maternal mortality rate was unusually low at 3.81 per 1,000 live births. The provision of 3,000,000 new and decent houses, it is stated, "is probably the greatest contribution which this generation has made to better health." Since 1901–10 the standardized mortality from pulmonary tuberculosis has been more than halved, while the rate for the non-pulmonary form is now actually little more than a quarter of what it was then. Emphasis is laid on the new service of midwives provided under the Midwives Act, 1936, and on the expectation of an improved maternity service as the result of the Ministry's and the local authorities' reactions to the recently issued report on an Investigation into Maternal Mortality. It is pointed out that developments in public health and social services are rarely dramatic in their coming. Advances are made, gaps filled up, machinery overhauled, and salients smoothed. The Minister is justly pleased with the general effect, and is determined to promote a campaign of public education extending over six months of the coming winter, designed to induce the public to make fuller use of the public health services. But there are serious gaps remaining to be filled and some salients from which a retirement might possibly be contemplated. Extension of medical benefit requires to be carried much further than the "under sixteens," and new types of provision of a specialist character for insured persons are rather urgently required. The whole question of the relation of the clinical services of local authorities to insurance and private practice needs serious consideration. The proposal to amend the rules for midwives so as to establish a service of semi-specialist obstetricians is a bad form of the advance by capturing salients, since it does nothing to bring even these elect into ante-natal contact with the women they may be summoned to confine. The Ministry's regard for the continuity of medical care of the sick poor through local panels of practitioners has been lukewarm; nor does it recognize as of public health importance the public medical services organized by the profession. In a field more remote from medical practice, the anomaly that such records of sickness as insurance provides are buried in the archives of friendly and approved societies ought to be faced after a quarter of a century of its persistence. The dissatisfaction, too,

which younger members of the public health service freely express as to the existing machinery for filling vacancies in that service deserves notice.

The medical profession, through the British Medical Association, has fostered and will continue to support efforts in behalf of the public health. It welcomes the evidence this report affords of the general soundness of the measures which have been taken. Advance by salients and the filling of gaps are good tactics, but the Association believes that they should be part of a carefully thought-out strategic plan, a plan in the preparation of which it is ready to help, in conference both with the Ministry and with the local authorities, who are shouldering health responsibilities in the exercise of which they would be wise to consider advice from every well-informed quarter.

TOXOPLASMA AND PROBLEMS OF IMMUNITY

The subject of the toxoplasma is hardly one with which the majority of medical men are familiar. Yet it is not unimportant, for these parasites occur quite commonly as latent infections in several experimental animals—rabbit, guinea-pig, mouse—introducing a complication in transmission experiments; and they have occasionally been reported as causing disease in man. It is true that most of these reports have been unconvincing, but Bland's evidence[1] that toxoplasma are the cause of glandular fever cannot be so lightly dismissed and certainly calls for further investigation. Toxoplasma are small oval or pyriform parasites about 6 μ × 3 μ in size, with definite nucleus and protozoan appearance. They have been described in a number of species of birds, including the sparrow, *Passer domesticus*, and have been observed in the rabbit in Brazil by Splendore[2] and by Nicolle and Manceaux[3] in the African gondi, a small mammal of the desert. As already indicated, their occurrence in laboratory animals has been noted by several workers, some of whom have made these parasites a subject of special study (Levaditi *et al.*[4]). Despite this the taxonomic position of toxoplasma remains obscure, and, apart from saying that they are intracellular parasites most commonly found in the liver and spleen and that they can multiply by longitudinal division, not very much is known.

The most recent addition to the literature of this subject is a short article by A. B. Sabin and P. K. Olitsky.[5] These workers encountered toxoplasma in the course of their investigations on viruses, and, struck by the fact that many of the problems presented by the study of these highly organized parasites are very similar to those met with in the investigation of filterable viruses, they decided to study toxoplasma more closely. Perhaps their most interesting observations and comments concern the question of immunity to these parasites. They observed, as did Bland, that the inoculated monkey develops a febrile not-fatal illness, recovery from which is associated with immunity to reinfection. They further noted the presence of neutralizing antibody in the blood, the test for which consisted of making mixtures of serum and a suspension of toxoplasm-containing tissue and injecting it intracerebrally or intraperitoneally into mice or intradermally into rabbits. It will be recalled that a year or two back Sabin[6] published a series of papers in which he claimed to show that virus and neutralizing antibody did not unite *in vitro*, and concluded that the function of neutralizing antibody was not to unite with the virus but with the susceptible tissue cells, which it protected in so doing. He further suggested that the antigen responsible for the production of neutralizing antibody was not a component antigen of the virus but the product of the tissues of the infected host. According to Sabin the mechanisms of immunity to a virus and to a bacterium differed fundamentally. This view is now supported by experiments made with toxoplasma. Sabin and Olitsky find that in neutral mixtures of immune serum and toxoplasma the parasites undergo no agglutination or lysis even after several hours' incubation, and that the toxoplasma recovered from such mixtures by centrifugation and freed from serum are fully infective. They further draw attention to the solid immunity which may be found in recovered rabbits, despite the fact that little or no neutralizing antibody is demonstrable in their serum, an immunity which they consider to be solely an affair of the tissues.

It may be that a true tissue immunity unassociated with antibody does occur. Possibly the immunity to the virus of poliomyelitis may be of this nature, and the "interference phenomenon" demonstrated by Salaman[7] in the case of the X virus of potato and by Findlay and MacCallum[8] with yellow fever virus is probably an example of a tissue immunity. But the mere inability to demonstrate free neutralizing antibody in the blood is not sufficient reason for assuming the existence of a pure tissue immunity. And as far as the union of virus and neutralizing antibody *in vitro* is concerned might it not be that an optimum balance between antigen and antibody was necessary for the demonstration of this union? This

emerges clearly from the experiments of M. H. Salaman,[9] which demonstrate that union between vaccinia virus and its neutralizing antibody does occur *in vitro*, but that this might easily be missed unless the correct absorbing dose of antigen were used. Furthermore, it would seem wise before drawing comparisons between the action of protective antibody on viruses and on bacteria to make quite sure what really does take place in the latter case, for recent work by Enders and Shaffer[10] has shown that what some have thought to be phenomena peculiar to viruses and their antisera can be demonstrated equally well with Type III pneumococcus and its antiserum.

A CIRCULAR TO PREFECTS

The establishment of a co-ordinated scheme of health government in a new country where the ground is unencumbered by relics of any previous ventures may be a comparatively simple task. But where existing organizations of long standing require preliminary absorption or extinction the sure founding of a new system is not so easy. Each successive need may have been met in the past by legislative or other changes, each good enough in its day and still of some value, but on a general view revealing much inequality of distribution, some areas enjoying an embarrassment of service while others are left untended. In any well-governed country which can look back to a historic past the natural tendency is to give co-ordination a trial before resorting to more drastic measures. This has been evident in France lately, when the Minister of Health issued a Circular to Prefects on the co-ordination of services and institutions. He had observed, despite remonstrances by his predecessors in office, a tendency in too many departments of the country to isolated action by hospital boards, relief agencies, and others. His problem was how to bring these various bodies into touch with one another. He resolved to use the financial lever, and accordingly issued his circular announcing that there would be no more grants in aid other than to services affiliated to the official social hygiene bureau of the area, which would thus co-ordinate all their activities. In cases where this could not be done for any reason the Prefect was to appoint without delay a local co-ordinating committee for the same purpose.

The circular is of interest not only as an administrative instrument but also on account of an article by the Minister, in collaboration with the head of a department, which serves as an introduction to the circular as printed in the *Revue d'Hygiène*.[11] In this paper the Minister explores the fundamentals of communal health control. The essential conflict of interest between the individual and the community, he says, has been exacerbated by repressive sanitary legislation, but it is the aim of hygiene to restrain anti-social inclinations by ministering to the physical, mental, and social diseases of the people. In all public health work he urges the importance of the social outlook. The medical officer should have experience of family practice, which gives social insight. The health visitor should be fitted for both hygienic and social duties. The welfare centre can never effectively safeguard the health of the persons who frequent it unless it can extend its influence into their homes. Domestic hygiene and social service are inseparably intertwined, and the centre itself should work in liaison with the public assistance authority. In the field of mental prophylaxis, while recognizing that good may result from early treatment in clinics attached to mental hospitals, the Minister considers that in many cases still earlier intervention is required. The trained health visitor, as she moves among the homes of the people, is well fitted to bring to light unhappy or delinquent children who are oppressed by their home conditions and whose parents stand in need of either advice or warning. The reconciliation of traditional medicine with technical medical science is a problem in France as in other countries, but free choice of doctor should be maintained and a direct financial relationship should exist between doctor and patient. Vaccination, disinfection, and the removal of infectious cases to hospital no longer comprise the entire field of public health. Uncertainty for the morrow, whether individual or national, is one of the main causes of the physical, mental, and moral sickness of the time. For such conditions social service as an integral component of public hygiene may do much.

AURICULAR FIBRILLATION AND CONGESTIVE FAILURE WITHOUT ORGANIC HEART DISEASE

More than any other arrhythmia auricular fibrillation is a symptom of organic heart disease, especially when it lasts more than a few days. There are, however, exceptions to this rule, notably when fibrillation is associated with toxic goitre, where an alteration in the functions of the myocardium without structural change is assumed, since removal of the offending gland, if not too long delayed, is quickly followed in most cases by a return of normal rhythm. Short paroxysms of fibrillation are not at all uncommon in infections, especially in pneumonia, apart from any structural disease of the heart. In another group of cases fibrillation is an isolated symptom, unassociated with any discoverable disease of the heart or other organ; here the arrhythmia may be a chance discovery, or attention may be drawn to it through palpitation. Most often in this group the condition is of short duration, occurring in short paroxysms; but it may be permanent. Generally the irregularity is well borne, the ventricular rate being not very rapid. An exceptional case believed to be of this type, and in which congestive failure developed, is reported by Brill.[1] His patient, a woman aged 43, had no rheumatic history; blood pressure was normal; there was no arteriosclerosis and no goitre; before treatment

[1] *Amer. Heart J.*, February 13, 1937, p. 175.

the ventricular rate was 160, and from the history it appeared probable that the arrhythmia had been present for several weeks, the onset being preceded shortly by a sinusitis. After digitalization congestion quickly disappeared and the ventricle slowed to 85 per minute; a trial dose of quinidine (3 grains) unexpectedly restored normal rhythm; the patient was soon able to resume a normal life, and has remained well during subsequent observation for one year. Electrocardiograms during the attack revealed no abnormality apart from the rhythm and digitalis effects; radiographs taken after the disappearance of failure showed a cardiac shadow within the normal limits of size and shape. The investigations carried out on this patient would appear to exclude all the usual causes of congestive failure with fibrillation: absence of clinical and radiographic signs of mitral stenosis and the subsequent course are against rheumatic heart disease; there was no evidence of coronary occlusion, nor of hypertension or toxic goitre. This case, in which it is presumed that fibrillation with a rapid ventricle had been present for some time before severe symptoms developed, seems best explained by analogy with the rare cases of paroxysmal tachycardia where, though no organic heart disease exists, a long-continued rapid beating finally leads to myocardial exhaustion. The only apparent explanation for the abnormal rhythm was the sinus infection which shortly preceded it. The use of quinidine, though now regarded as unjustifiable in the presence of severe organic heart disease, as is usual when there is congestion, is held to be rational in the above case, in which, after the relief of symptoms, no structural lesion was found.

THE HEADACHES OF LADY ANNE CONWAY

Lady Anne Conway died in 1679, a life-long sufferer day and night from severe headaches, which in her latter years were associated with "fits." In addition to the constant pain she suffered much at the hands of many physicians, for she was treated by her kinsman, Dr. William Harvey, by Dr. Willis, by Sir Theodore Mayerne, by Van Helmont, and, as she lived at Ragley, seven miles from Stratford-on-Avon, by Dr. Stubbs, the local practitioner. For a time she passed under the hands of Valentine Greatrakes, a quack who promised much by his method of "stroaking," but failed to give her relief. In spite of such a grave disability Lady Conway became a great metaphysician, and Dr. Henry Moore of Cambridge, "who was almost perpetually in her chamber," used to speak of her as his "heroine pupil." It is said that her ruling passion was for the most abstruse treatises on philosophy and mysticism. Dr. Macdonald Critchley, in the April number of the *King's College Hospital Gazette*, reconsiders the nature of her illness, and arrives at the conclusion, as Dr. Gilbert R. Owen had done before him, that Lady Conway probably suffered from major migraine and not from tumour, aneurysm, or hydrocephalus, as has been suggested at various times. The Rev. John Ward, who was the contemporary vicar of Stratford-on-Avon, reports: "My Lady Conway hath a tumour on one side and a scirrhus of ye Mesenterie as is supposed, as Mr. Stubbs says. She came into this miserie by a brother of hers who had some skill in chymisterie and tried experiments uppon her." She lies in the Arrow churchyard, just outside the gates of Ragley Park. She died while her husband was in Ireland, and Van Helmont caused her body to be preserved in a coffin filled with spirits of wine and provided with a glass cover that Viscount Conway might see her face when he returned to England.

THE MECHANISM OF ACCOMMODATION

Whether from satisfaction with the achievements of nineteenth century physics or from sheer irritability at the unsuspected complexities of the eye, Helmholtz considered it a very imperfect optical instrument which no respectable optical manufacturer would have made. One of the complexities of the eye is the faculty of accommodation. That some mechanism exists whereby objects at different distances can be clearly focused at the retina was, of course, appreciated in antiquity, and the failure of this mechanism after middle life was a serious matter when glasses as an artificial means of correcting it were not known. No clear distinction between presbyopia and hypermetropia was achieved until the days of Donders, and it was only in the second half of the last century that the puzzling fact that some young people benefit from glasses generally used by old people—"old sight" in young people—was clearly understood. As to the nature of accommodation itself, though Scheiner proved it conclusively in 1619 with the simple experiment of looking at a needle through two pinholes, subsequent observers advanced a host of arguments to dispute not only various explanations of accommodation but its very existence. When accommodation was finally accepted as a fact it was left to the genius of Thomas Young to reduce a mass of hypothetical explanations to one which implicated the lens, and the lens only, as the site where changes occurred to allow the focusing of both distant and near objects; and since his days the dispute has centred round the exact mechanism whereby the lens changes its refractive power. Thomas Young himself held that the lens had muscle fibres which made changes in contour possible, but the explanation which finally came to be accepted almost to the exclusion of all other views was the one advanced by Helmholtz in the fifties of the last century. Underlying Helmholtz's theory was the conception that the lens was in a state of constant tension during rest; many later workers regarded this idea as unphysiological, and the arguments on the subject have often assumed a metaphysical tinge. The broad facts of Helmholtz's explanation have, however, held their ground; what has been disputed is the relative value of different factors. Largely owing to the work of Tscherning the exact changes in the contour of the lens during accommodation can now be more clearly appreciated. The uniform increase in spherical contour postulated by Helmholtz has given way to the

demonstrable formation of something like a central anterior lenticonus with a flattening of the periphery. Such a deformation of the lens during accommodation does not fit in with Helmholtz's conception that contraction of the ciliary body, leading to relaxation of the suspensory ligament, allows the lens previously under tension to assume its normal globular form. Modern views emphasize not the elastic nature of the lens but its plasticity, and Helmholtz's explanation does not solve these difficulties. Granted the plasticity of the lens, a host of theories have been advanced to explain the peculiar deformation that the lens undergoes during accommodation. Pressure from the vitreous and pressure from the aqueous are but two of these. Of late years much attention has been paid to the capsule of the lens as the means of moulding the plastic lens. The work of Hess and Gullstrand was ably elaborated by Fincham, who held that the deformation of the lens seen in accommodation could be explained by the differences in thickness seen in the capsule at different points; a central anterior lenticonus follows naturally since the anterior central part of the capsule is the thinnest. Thus, while the essential details of Helmholtz's theory still stand, the appreciation of the part that the capsule plays is held to resolve some of the difficulties in the original theory. The stress upon the part played by the capsule has its origin in theoretical conjectures. The mass of laborious work that Fincham has brought forward in support of this explanation is ably summarized by him in a monograph.[1] Most of the work has been published as individual articles from time to time as the facts accumulated. The student of the subject will be glad to have it in the present form free from the repetition that a series of isolated articles must of necessity contain.

THE NATION'S CRIMINALS

"The Amazing Dr. Clitterhouse," in the popular play now running in London, continually raises his glass to "Crime and Research." Had he possessed himself of the Home Office annual report on criminal statistics[2] he might have found enough to engage him without pursuing the adventures among crooks which led to his own undoing. When it is stated that in 1935 (the latest statistical year) over three-quarters of a million people were found guilty in the courts of some offence or other, it seems a big proportion of the population of 35 million (excluding children under 10) of England and Wales. More than half these persons, however, were traffic offenders—although, of course, that may mean in some cases an offence as heinous as anything in the calendar. The bulk of the remainder were guilty of non-indictable offences, such as drunkenness and breaches of by-laws, and only 70,000 had committed crime, chiefly theft. Of the 70,000 indicted more than 60,000 were males, three-fourths of them being under 30 years of age. Larceny appears to be the crime of youth, frauds and false pretences the crimes of maturity. Crimes against the person have diminished during the present century. The number of cases of malicious wounding is only a fraction of what it was a generation ago, though there is an increasing tendency for violence to accompany crimes against property. Rape and indecent assault are less frequent, but the number of cases of defilement of girls under 16 has increased. Leaving out bigamy, which is grouped among sexual offences in the police records, such offences have fallen from an annual average of 779 for the years 1900-4 to 500 for the years 1931-5. The number of persons in England and Wales who committed suicide in 1935 was just over 5,000. Far more males than females commit suicide, but the number of those who make the attempt and do not succeed is more nearly equal as between the sexes. The suicide age for women is between 40 and 50; for men it is over 60. The number of criminal lunatics (the word has not passed out of the language when mental disorder is linked with crime) received at Broadmoor and at county and borough mental hospitals was 127, of whom forty-five were "King's pleasure lunatics," being found either insane on arraignment or "Guilty but insane," and the others were "Secretary of State's lunatics," being found insane after conviction. Perhaps more important sociologically than the crime is the manner of dealing with it. In view of the Home Secretary's decision to appoint a committee to review the question of corporal punishment, on which such a variety of views were put forward at the recent Annual Representative Meeting, it is interesting to learn exactly how often the courts impose such sentences. Corporal punishment may be inflicted as an additional penalty for robbery with violence; also for any attempt to choke or suffocate (but not for otherwise assaulting) a person with intent to commit an indictable offence such as rape; for being an "incorrigible rogue," though in fact the only offence coming within this category for which corporal punishment has been ordered in recent years is indecent exposure; and in the case of male persons living on the earnings of prostitution or soliciting for immoral purposes. There is also power to inflict whipping on boys between 14 and 16 for malicious damage, arson, and larceny. In the ten years from 1926 to 1935 sentences of corporal punishment have been imposed by the courts of assize and quarter sessions in 253 cases, of which number 235 were cases of robbery with violence, 129 of the offenders being sentenced to the cat and the remainder to the birch. Another class of cases is that in which corporal punishment—not more than six strokes of the birch rod—is inflicted by juvenile courts. The number of such sentences passed in 1935 was 218, and the ten-year average has been below 200. The great majority of the one thousand juvenile courts in England and Wales, including the metropolitan courts and the courts of the principal towns, do not use the method. The 218 boys who were birched during the year under review were not necessarily worse than their fellows, but they had the ill luck to come before the few courts—mostly in the counties and smaller towns—which have not learned to spare the rod.

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

DEPTH OF ANAESTHESIA FOR VARIOUS OPERATIONS

BY

C. LANGTON HEWER, M.B., B.S., D.A.

It is frequently stated that the least possible quantity of the least toxic drug or combination of drugs should be administered to produce just sufficient depth of anaesthesia for any given operation. Like most generalizations this is only a half-truth. At first sight it appears most laudable to produce the lightest degree of narcosis which will enable the surgeon to perform his task, as it is evident that the less a patient inhales of a toxic drug the less there is to eliminate, and consequently metabolic changes will be minimized.

Operative Shock

In practice, however, a formidable difficulty arises. One of the causes of operative shock is the effect of traumatic stimuli on the central nervous system. This "reflex" type of shock was at one time thought to be due to exhaustion of the vasomotor centre from excessive stimulation. The modern view, however, is that there is a definite inhibition of the centre by certain afferent stimuli. Whatever the actual mechanism may be, this type of shock can be greatly diminished by deep general anaesthesia and practically abolished by suitable local analgesia which prevents the stimuli from reaching the central nervous system. A good example of the first method is afforded by the operation of osteoclasis for rickets. If the child is lightly anaesthetized he may show signs of severe shock immediately after fracture of the bones, but if he is deeply etherized the pulse rate and blood pressure may scarcely change. As examples of the protection afforded by nerve-blocking, a disarticulation through the hip-joint or a hind-quarter amputation may be cited. The immediate effect on a patient's condition may be almost unnoticeable under spinal analgesia. As a rule it is not possible for the general practitioner to perform combined methods of general and local anaesthesia, so that in this article it will be assumed that he only has the simpler forms of general anaesthesia at his disposal.

Abolition of Reflexes

The question of reflexes must next be considered. It is obvious that the normal response to stimuli must be abolished, but what of the protective cough reflex? If there is any possibility of liquid or solid material reaching the air passages during the performance of the operation either the anaesthesia must be kept sufficiently light to preserve the protective cough reflex, or adequate provision must be made to prevent aspiration, such as by endotracheal anaesthesia, with packing, suction, etc. It is possible for the operation to induce inconvenient reflexes unless anaesthesia is extremely deep. For example, if an inflamed bladder is distended with fluid before cystoscopy straining will occur unless the narcosis is carried to a very deep plane.

In certain cases a light anaesthesia may be more dangerous than a deep one. For instance, if chloroform or a mixture containing it is being used there is an increased risk of primary cardiac failure if the patient is incompletely anaesthetized, the most dangerous period being at the end of the second stage. In most prolonged operations there are times when the anaesthesia can be appreciably lightened without detriment to the surgeon's work, and a careful anaesthetist who takes advantage of these periods may save his patient much unpleasantness afterwards by a quicker recovery and freedom from after-effects.

Lastly, we have to remember that deep anaesthesia is not always accompanied by complete muscular relaxation. Straining may actually occur during overdosage if the airway is partially obstructed. Conversely, the anaesthetist who is always careful to maintain a perfectly clear airway will find that he can obtain adequate relaxation at a surprisingly light level of narcosis.

Passing next from the general to the particular, we have to consider the depth of anaesthesia necessary for certain common operations.

Minor Operations

Small surgical proceedings, such as circumcision, myringotomy, the incision of whitlows, the removal of superficial tumours, etc., do not give rise to an appreciable amount of shock and can consequently be performed under the lightest anaesthesia which will prevent reflex movements. The only proviso is that no chloroform or mixture containing it may be employed.

Dental Extractions

The removal of teeth does not require muscular relaxation provided that a prop or gag has been inserted in the mouth before anaesthesia. In children the single-dose ethyl-chloride or di-vinyl ether technique is usually adequate. It sometimes happens that the depth of anaesthesia is such that the cough reflex is abolished. It is always wise, therefore, to insert a sponge or pack to obviate any chance of the inspiration of fragments of teeth. For short extractions in adults gas or nasal gas and air is the usual method. Although the cough reflex is generally unimpaired it is prudent to employ packing as an additional safeguard.

If a long dental operation is proposed the patient should, if possible, be removed to a hospital or nursing home and anaesthesia be conducted by the nasal endotracheal route, with packing. This is the only safe method of securing a smooth anaesthesia for an indefinite period. A plane of light third-stage narcosis will suffice for this type of operation. The actual techniques are discussed in another article.

Removal of Tonsils and Adenoids

The rapid guillotine method of tonsillectomy in children is as a rule performed under the single-dose ethyl-chloride or di-vinyl ether technique, preceded where possible by oral nembutal or rectal paraldehyde. Unfortunately the majority of such operations are performed upon out-patients and adequate premedication is impossible. A rather deeper anaesthesia is needed than for dental extractions, as the pharyngeal reflex should be abolished. Immediately after the removal of the second tonsil the child should be turned on to his side and allowed to come round until the cough reflex returns before the adenoids are

scraped. If any solid matter should then slip off the curette and be inhaled it will be immediately coughed up.

If the tonsils are to be dissected continuous anaesthesia is necessary. The simplest method is the pharyngeal insufflation of ether vapour through the tube on the tongue-depressor of a Davis gag. Anaesthesia must be sufficiently deep to enable the surgeon to exert traction on the tonsils without causing retching. With this plane of anaesthesia the cough reflex may be absent, so that blood must be prevented from reaching the larynx. This can be accomplished by suction and by the position of the patient. The latter varies with the individual surgeon, but is usually the "thyroid" position with extended head, or the lateral "Butlin" position with the head low. The only certain method of protecting the air passages from blood and debris is the nasal endotracheal technique with a gauze pack. Neither the tube nor the packing must be removed at the end of the operation until the cough reflex has returned.

Nasal Surgery

Short procedures such as antral puncture and turbinectomy can be done under a "single dose" anaesthetic technique.

In longer intranasal operations, such as sinus drainage or submucous resection of the septum, continuous anaesthesia is needed. Pharyngeal insufflation with a post-nasal pack or Shipway's ballooned airway is only safe if the cough reflex is preserved, since it is impossible to be certain that no blood will leak past the pack. Oral endotracheal anaesthesia with gauze packing or a ballooned tube is undoubtedly the method of choice, and an even level of narcosis can then be maintained with perfect safety.

Abdominal Surgery

Comparatively minor procedures such as operations for hernia and varicocele require little relaxation and can be performed under light third-stage narcosis. Extensive intra-abdominal operations, on the other hand, demand good relaxation. The nearer the incision is to the diaphragm the greater will be the respiratory excursion and consequently the greater the need for shallow respiration. The suturing of hollow viscera is both tedious and difficult if the suture line is moving over an extensive range. Furthermore, traction on the diaphragmatic attachments tends to cause reflex laryngeal spasm with consequent laboured breathing and poor relaxation. For these reasons an ordinary inhalation anaesthesia may not prove satisfactory for such operations as gastro-enterostomy, partial gastrectomy, and cholecystectomy. A thorough cocainization of the glottis may help to obviate laryngeal spasm, but the only certain preventive is the passage of an endotracheal tube. In many cases it is possible to use this technique without additional apparatus by means of "blind" nasal intubation, the administration being continued as before with a mask. A "gas" mixture is naturally preferable if an apparatus is available.

Pelvic and lower abdominal operations, such as appendicectomy and hysterectomy, can generally be performed satisfactorily with a straightforward inhalation anaesthesia carried well into the third stage. Prostatectomy, if done under general anaesthesia, necessitates the absolute minimum of ether, as the patient is practically always a poor risk with damaged kidneys, and often suffers in addition from chronic bronchitis.

There are three stages in an intra-abdominal operation when a deep plane of narcosis is necessary. They are (1) on opening the peritoneal cavity, (2) during traction on peritoneal attachments, and (3) on closing the peritoneum. The "sewing-up" must be anticipated by some minutes as it is impossible to deepen the anaesthesia suddenly, and straining at this stage is particularly trying. Similarly, a surgeon who without warning suddenly explores the gall-bladder, having finished an appendicectomy, may upset a lightly anaesthetized patient very badly. Renal operations performed through a lateral incision do not require such deep anaesthesia, as the peritoneum is not opened.

Thoracic Surgery

Minor operations upon the thoracic wall, such as the excision of breast tumours and the application of radium needles, can be carried out satisfactorily under quite light anaesthesia. A good technique is fairly heavy premedication followed by gas and oxygen.

Thoracoplasty can be performed by the same method if sputum is not excessive, but owing to the fact that the patients have a poor vital capacity and are lying on their sound sides an excess of oxygen should be used. This will necessitate the addition of small quantities of di-vinyl ether or, failing this, of chloroform. If cyclopropane is available and the diathermic cautery is not employed, an even better anaesthesia will ensue. The same remarks apply to the drainage of acute empyema if this is to be carried out under general anaesthesia.

Should a patient be coughing up an excessive amount of sputum (as in bronchiectasis) and an extensive thoracic operation be contemplated, the cough reflex must either be retained (as in high spinal or other local technique), or the fluid must be confined to the affected lung (as in intra-bronchial anaesthesia) or evacuated by tracheal or bronchial suction combined with endotracheal anaesthesia. These procedures are mostly outside the scope of the general practitioner and will not be considered further.

Thyroid Surgery

Operations for the relief of toxic goitre have recently become so frequent that some reference must be made to them. Since tracheitis is one of the most frequent sequelae the anaesthetic chosen must not aggravate it. Consequently the use of ether and the passage of tracheal tubes should be avoided unless respiratory obstruction is present. Since relaxation is not necessary a light level of narcosis is adequate, and the avoidance of toxic drugs such as ether and chloroform may just turn the scale in favour of an extremely ill patient. A good technique is heavy premedication or basal narcosis with avertin, followed by pure nitrous oxide and oxygen. The surgeon may prefer an additional infiltration with novocain and adrenaline or adrenaline solution alone (1 in 500,000) in order to separate tissue planes and minimize capillary oozing, but this is not essential. In total thyroidectomy for congestive heart failure cyclopropane is indicated, but for ordinary cases its employment causes excessive bleeding. (The depth of anaesthesia desirable in obstetrical practice is considered in another article of this series.)

The French Ministry of Public Health has instructed the venereal disease services to issue health passports to their patients. Each "carnet médical personnel" will be identified by a number instead of the patient's name and will contain the relevant data concerning diagnosis, clinical and laboratory findings, and instructions to be followed. When a patient leaves a venereal disease service this passport is to be given to him or to his new doctor.

ONE HUNDRED AND FIFTH ANNUAL MEETING

of the

British Medical Association

HELD IN BELFAST, JULY, 1937

THE SECTIONS

SUMMARY OF PROCEEDINGS

During the next few months there will be published in the BRITISH MEDICAL JOURNAL *the opening papers communicated to the Scientific Sections of the Annual Meeting at Belfast. The reports of discussions, concluded from last week* (*p.* 288), *are intended to give members who were not present a general idea of the proceedings.*

COMBINED SECTIONS OF MEDICINE AND SURGERY

Friday, July 23

Abscess of the Lung

With Professor W. W. D. THOMSON in the chair, the discussion on "Abscess of the Lung" was opened by Dr. L. S. T. BURRELL. He held that this disease was a very serious one and frequently fatal. A considerable proportion of single lung abscesses followed operations on the nose, throat, or teeth. Frequently the onset was insidious and even afebrile, the earliest symptoms often amounting to no more than malaise and a nasty taste in the mouth. Clubbing of the fingers was an early sign, while local evidence in the lung might only appear later. The speaker stressed the necessity of localization by *x*-ray films in different positions, but considered that stereoscopic radiographs were apt to be misleading. Although it had been said that the use of an exploring needle was dangerous owing to the risk of infecting a healthy pleura, he had never known it happen; at the same time he agreed that it was unnecessary to explore an abscess by this means. Treatment by postural drainage was best carried out by the use of the bed devised by the late Mr. H. P. Nelson; a full six weeks should be allowed before surgical treatment was considered. Bronchoscopic methods did little more than hurry drainage.

Mr. J. E. H. ROBERTS agreed that suppuration in the lung was extremely serious; delay in the diagnosis often contributed to the gravity, and the use of the tomograph might help to eliminate this factor. An abscess was always close to the surface of the affected lobe; only partial evacuation followed the opening into small bronchi, and large sloughs that could not have passed even through a main bronchus were commonly found at operation; further, the vessels in the walls of chronic abscesses became progressively obliterated. For these reasons he considered that postural drainage might fail owing to the small openings out of the abscess allowing only liquid pus to escape. Artificial pneumothorax was inadvisable, and bronchoscopic drainage had only a limited application. Mr. Roberts held that postural drainage and other medical measures might be continued as long as there was progressive improvement as judged by clinical and radiological methods. Failing this, operation should not be delayed longer than two weeks. External drainage by a two-stage operation under cyclopropane was the method he advised in the earlier stages. As often as not the opening of the thorax revealed thickening of the rib periosteum and opacity of the pleura, and the operation could then be concluded at the same sitting by incision and drainage of the lung. Lobectomy might be the best procedure in more chronic lung abscesses.

Dr. PETER KERLEY spoke of the radiology of lung abscess, and insisted that lateral views were important, in the lying as well as in the erect posture. Since signs might be indefinite, radiological control at intervals of three days was advisable. The tomograph promised to be of great help in the localization of lung abscesses. Radiography might help to distinguish an abscess due to new growth, since in such cases part of the wall of the cavity often showed no pneumonitis. Chronic suppuration might cause local malignant disease. If an *x*-ray showed cavities forming very rapidly a diagnosis of acute pneumonic phthisis should be considered rather than lung abscess.

Dr. CARL SEMB (Oslo) agreed that surgical intervention in lung abscess was often delayed too long. The patient should be under close observation from the onset of the illness, medical treatment being adopted during the first week or two. Using the same criteria for surgical intervention as those laid down by Mr. Roberts, he considered that operation in one or two stages should be undertaken within three to five weeks unless treatment by medical means was producing progressive benefit. Dr. Semb related his experience of seventy-four cases of pulmonary suppuration, which he considered was a not uncommon cause of empyema.

Dr. GEOFFREY MARSHALL regarded bronchial obstruction as a common cause of lung abscess. Dental extractions and anaesthetics were sometimes followed by pulmonary suppuration, and he had seen this condition caused by the unwise administration of morphine or hyoscine to control respiratory distress in asthma. Patients sometimes coughed up an abscess during transit to hospital or nursing home, and this had encouraged him to adopt what he termed "percussion drainage"; in this procedure the patient's chest was vigorously pummelled several times a day with the object of provoking drainage through the bronchi. An initial bronchoscopy should be made in all cases, but he felt that repeated bronchoscopic drainage was a useless method of treatment. Conservative treatment should be adopted for two weeks, and operation should then be delayed only if continued improvement was in progress with a leucocyte count below 12,000 per c.mm.

Dr. W. BURTON WOOD took the view that the bronchi were to be considered as "permanent air-shafts and occasional drains." The best treatment of lung abscess was drainage through these natural channels. In his view postural drainage was not always given a fair trial. Bronchoscopic drainage was a valuable means of treatment, and he had often performed this in order to overcome temporary blockage of the bronchi in the course of natural drainage. Of his group of forty-five cases of pulmonary suppuration twelve were considered to be suffering from septic pneumonitis. Medical treatment was adopted in twelve, all of whom recovered. Bronchoscopic drainage was employed in eight, while five recovered after a complicating empyema had been drained. Surgical drainage in eight cases resulted in two deaths directly due to the operation, while the remainder recovered.

Professor F. W. ARCHIBALD (Montreal) grouped cases of lung abscess into those caused by aspiration and those produced by infected emboli. The former were associated with pneumonitis and often followed bronchopneumonia. Embolism caused little surrounding reaction and good healing was possible, since the neighbouring lung retained its elasticity. He commented on the disparity of the views expressed regarding treatment: probably lobectomy was the best treatment when suppuration due to aspiration had continued two or three months.

Mr. G. R. B. PURCE (Belfast) had found no obvious cause in forty-one of his sixty-six cases of lung abscess. Unlike Maxwell, who recorded forty-three cases following pneumonia out of a total of 199, he had had no case from this cause. Embolism was a more frequent basis of abscess than was generally recognized. The bacteriology of the putrid abscess always included anaerobic streptococci, fusiform bacilli, and a spirillum. Two-thirds of all abscesses involved the lower lobes, the frequency being equal on the two sides. Medical and surgical treatment must be complementary. A surgical emergency arose if perforation of the pleura occurred before the abscess ruptured through natural channels. After this had occurred a perseverance in medical treatment resulted in cure in about 70 per cent. of cases. If in six to eight weeks continued resolution was not evident then operation should be undertaken. An abscess of many months' duration could only be dealt with surgically, and the mortality was then very high.

Mr. PHILIP ALLISON (Leeds) thought that there should be no hard-and-fast distinction between medical and surgical treatment; in every case both forms of treatment had to be applied at different stages. He disagreed with Mr. Roberts on the matter of bronchoscopic drainage, and said that in his experience this procedure was frequently successful in assisting the passage of pus through a large draining bronchus. If operation had to be undertaken complete removal of the roof of the cavity was essential. Too prolonged treatment by medical means often resulted in bronchiectasis.

Dr. BURRELL answered several questions that had been asked. He commented on the approximation of the medical and surgical views on the principles of treatment. Mr. ROBERTS also replied, with special reference to the statistics quoted by Mr. Purce. He thought that the failures of surgical treatment should be added to those of medical treatment in assessing the failures of conservative measures, since the latter had been tried without avail in the first instance. In any case he felt strongly that the results of present methods were so bad that the possibilities of earlier operation ought to be tried out.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Friday, July 23

Forceps Delivery

In the absence of Professor JOSEPH DE LEE (Chicago), Professor C. G. LOWRY introduced Professor De Lee's film entitled "Forceps Operation, including Episiotomy and its Anatomy." The film was a talking one, and there was first a lecture given by Professor De Lee on the history and evolution of the obstetrical forceps, followed by a detailed description of the anatomy of episiotomy and its performance on a model. Then followed an excellent film of the delivery of the foetal head with forceps after the performance of episiotomy on the patient, and the film ended with a review of the case.

Breech Presentations

Mr. T. S. S. HOLMES (Belfast) then took the chair and Mr. H. I. MCCLURE (Belfast) read his and Mr. C. H. G. MACAFEE'S paper on a critical survey of 349 cases of breech delivery. The paper dealt with 349 consecutive cases seen in the Royal Maternity Hospital, Belfast, during the years 1932–6. The cases represented a frequency of 6.03 per cent. of all deliveries occurring in the hospital over the same period. In 638 of private cases the frequency was 2.5 per cent. Of the 349 cases 305 were primary breech presentations. There were seventeen cases of twins in which each child was delivered as a breech. Three Caesarean sections were necessary, otherwise delivery was effected by the classical methods. Tables were then given showing that the total number of primigravidae was 115 and multigravidae 217. The gross foetal mortality in the primiparae was 23.72 per cent., in multiparae 38.96 per cent. A further table showed the cases eliminated to obtain the corrected foetal mortality, which in primiparae was 10 per cent. and in multiparae 3.42 per cent., giving a total in both of 6.1 per cent. The paper then dealt with certain essential precautions which should be taken to reduce this mortality figure still further. External version should be done at any stage after the thirtieth week of pregnancy as soon as the breech presentation was discovered. The patient should be re-examined every week until the onset of labour. Of 134 patients upon whom this manœuvre was performed only one (0.74 per cent.) bore a stillborn child. An anaesthetic should not be administered lest undue force be employed and result in separation of the placenta. Non-intervention until the breech had ceased to advance was the policy to be followed. The posterior arm was brought down in the classical method of delivery, but the writers failed to agree with the usual instructions regarding the method of dealing with the anterior arm. The arm could, in the majority of cases, be easily brought down without rotation of the child's back and occiput across the hollow of the sacrum. Extraction of the after-coming head was accomplished by the usual methods, but they insisted on slow and gentle delivery to prevent tentorial tears.

In the discussion that followed Professor DANIEL DOUGAL (Manchester) said that he found himself in agreement with practically all that had been said. While admitting that the foetal death rate in breech cases was twice as great as in normal deliveries, he thought that the difficulties had been greatly exaggerated. External version was a most valuable contribution to the solution of the breech problem. He was very strongly opposed to early interference in breech cases with extended legs.

Mr. L. CARNAC RIVETT said he agreed almost entirely with the writers of the paper, especially in regard to the meddlesome midwifery of early pulling down of extended legs. He was not in favour of episiotomy. He often used an anaesthetic for version, as he found the greatest cause of difficulty was the mother's tense abdominal wall.

Dr. H. R. FREDERICK (Port Talbot) said that it bewildered the general practitioner to find views on the treatment of breech cases altering from year to year. Professor A. H. DAVIDSON (Dublin) held that the danger of breech delivery was overstressed. The important thing in a primiparous breech was to make sure there was no disproportion. If there was disproportion to any degree, then Caesarean section should be considered. The extended legs should not be brought down—they form a very good dilator of the birth canal. Dr. J. ARTHUR H. SHERWIN (Melbourne) also referred to Professor De Lee's film, and mentioned the *vis a tergo* which he had seen used to express the foetus out of the uterus to avert extension of the arms.

Professor LOWRY agreed with the views expressed by Professor Davidson as to the dangers of external version. It was a proceeding by no means free from risk. Dr. A. E. CHISHOLM (Dundee) emphasized the value of the application of lateral pads after version had been performed.

In addition to these speakers Professor E. C. CRICHTON (Capetown), Professor J. CHASSAR MOIR (Oxford), Dr. J. S. ENGLISH (Singapore), and Dr. A. FULLERTON (Batley) also spoke during the discussion.

Professor DAVIDSON then showed his coloured film of the operation of vaginal hysterectomy. He stressed the easy convalescence for the patient, and the bloodlessness and simple technique. He injected into and around the cervix a solution of 1 2 per cent. novocain with 10 minims to 100 c.cm. of 1 in 1,000 adrenaline.

Dr. KATHLEEN VAUGHAN then read an excellent and lucid paper on posture in childbirth, and showed several photographs of ancient steles showing the early methods of assisting parturition.

SECTION OF PATHOLOGY, BACTERIOLOGY, AND IMMUNOLOGY

Friday, July 23

Influenza: Four Years' Progress

The President, Sir THOMAS HOUSTON (Belfast), congratulated Professor S. P. Bedson on the conferment upon him of an honorary degree by the University of Belfast, and asked him to take the chair.

Dr. C. H. ANDREWES read his introductory paper entitled "Influenza: Four Years' Progress." He described the methods by which virus can be isolated from cases of influenza by ferret inoculation and its maintenance and behaviour in animals, and gave the reasons for regarding this virus as the cause of the disease. These included not only the isolation of the virus from cases in many different parts of the world, but the development of neutralizing antibodies during the course of the disease, and one well-authenticated case of the transmission of the disease from ferret to man after long-repeated passage in the former. Interest had been centred lately on attempts at active immunization, and he and his colleagues had shown that the titre of neutralizing antibodies could be markedly increased by a single injection of virus suspension from mouse lung. This method had been applied on a limited scale in human volunteers during last winter's epidemic, and although the results had been inconclusive owing to the outbreak of the disease among the inoculated individuals at so early a stage that immunization was incomplete, he was still hopeful that the method might prove of use, even in spite of the fact that different strains of the virus appeared not to be antigenically identical.

Dr. C. H. STUART-HARRIS described the results of a clinical study of influenza undertaken in connexion with the former speaker's work on its aetiology. The disease had to be distinguished from a type of febrile catarrh from which the influenza virus could not be recovered. A careful tabulation of the symptoms of both conditions showed that in some features they differed, notably in the fact that in influenza due to virus the onset was sudden with mainly constitutional disturbance, whereas in febrile catarrh the initial symptoms came on gradually and were referable especially to the upper air passages. The leucocyte count was of no diagnostic value, and post-influenzal debility had not been characteristic of the recent epidemic.

Dr. R. W. FAIRBROTHER (Manchester) reported the results of his study of the same epidemic in the North of England. Two methods were available for demonstrating immune bodies—the neutralization test and the study of complement-fixing antibodies. He and his colleagues had used the latter, and found that a titre of 1 in 4 or over was indicative of resistance to the infection; the test could therefore be used to distinguish those requiring immunization. In the event of an epidemic the successful immunization of the susceptibles would greatly reduce the disastrous effects of the outbreak. Experimental work on the immunization of mice had yielded encouraging results, but the application of similar vaccines to man had been disappointing. He and Dr. Hoyle had consequently been endeavouring to obtain a more satisfactory type of vaccine. The antigenic structure of the influenza virus was complex; it included both a "soluble substance," which resembled a haptene and was demonstrated by the complement-fixation test, and the elementary bodies, which were concerned in the neutralization test and were essential for immunization. They had treated elementary bodies in various ways—with formalin, phenol, and heat (50° C.)—and mice were protected by each type of vaccine. The results obtained in mice indicated that elementary body suspensions heated to 50° C. for thirty minutes and suspended in 0.5 per cent. phenol as preservative formed a convenient and useful immunizing agent. The preparation was almost non-infective, free from bacteria and extraneous material, and could be conserved at 0° C. for several weeks. Its effect on man had still to be investigated, but experiments on ferrets indicated that a high degree of protection would not be induced.

Dr. J. G. SCADDING described a clinical and bacteriological study of cases of influenza admitted to hospital during the recent outbreak. These had been classified into those without lung involvement, those with clinical but no *x*-ray signs of lung involvement, and those with distinct pneumonia; the last had been separated into five types, according to the severity of the condition and its distribution. Virus had been obtained from several of these cases, and a bacteriological examination of the sputum was made in all. Taken as a whole the types of bacteria found did not differ from those in non-influenzal infections of the respiratory tract, but there was a distinct relation between the nature of the lung involvement and the types of bacteria present. Cases with clinical but no *x*-ray signs of pneumonia were often infected by members of the *Neisseria* group, while the presence of pneumococci was associated with lobar consolidation. The speaker had formed the opinion that influenza was a descending infection of the respiratory tract which might be arrested at any level, and that bacterial infection might alter the picture in various ways. He also described the post-mortem findings in seven fatal cases; the characteristic features were tracheitis, interstitial inflammation, and sometimes necrosis of the alveolar walls leading to haemorrhage.

The CHAIRMAN (Professor Bedson) said that the existence of several antigenic types of the influenza virus certainly appeared to be a misfortune, but suggested that the neutralization test might possibly be exaggerating the differences between them. The absence of correlation between the results of the complement-fixation and neutralization tests corresponded to his own findings in psittacosis. Was the quantitative complement-fixation test really a measure of immunity?

Dr. C. E. VAN ROOYEN (Edinburgh) suggested that the intense degree of cellular parasitization by the influenza virus accounted for the liability to secondary bacterial infection in influenza. There was a similar liability in ectromelia and psittacosis. He had found the complement-fixation test of use in studies of vaccinia. The prospects for active immunization against influenza did not appear to him unfavourable, as others had thought. Was prontosil of any value in influenza?

Dr. ANDREWES, in reply, said that prontosil had been tried in experimental influenza in mice and found to be useless. The antigenic differences between strains of virus had been shown in mice to affect the results of immunization, and some human experiments suggested the same conclusion. He discussed the relative merits of the neutralization and complement-fixation tests, and pointed out that the latter does not distinguish between different strains of virus. It was important to know whether it could be relied on to indicate the degree of susceptibility. In view of the fact that artificial immunity is likely to be short-lived one difficulty in connexion with it was that of forecasting the epidemic for which it was required.

Dr. FAIRBROTHER, in reply, maintained that the complement-fixation test was significant, and pointed out that it is the only feasible test in a laboratory not lavishly equipped for such research. It might be possible to prepare a polyvalent virus vaccine.

Staphylococcal Infections in Man

Professor J. W. BIGGER (Dublin) opened a discussion on staphylococcal infections in man. Staphylococcal toxins had been known for many years to exist, but their full study was a recent development which had produced an extensive literature. He traced the discoveries leading up to this work, the main landmarks being the demonstration of the dermonecrotic toxin by Parker, the establishment of methods of producing toxin, and the Bundaberg disaster with the studies which ensued on it. The components and varieties of staphylococcus toxin as they are

now known were described. The effect of these discoveries was that it was now possible and desirable to treat severe and dangerous staphylococcal infections with an antitoxin, and to immunize actively in chronic infections with toxoid. The latter, to be effective, must contain all the components. Antibody titrations during treatment with toxoid were unnecessary, and the amount of antibody formation required to prevent infection varied in different individuals, possibly owing to differences in the condition of the skin. Staphylococcus vaccines might also be helpful.

Dr. H. J. PARISH (Beckenham) said that the antitoxin which was issued commercially in the British Isles neutralized the important toxic properties (lethal toxin, necrotoxin, α haemolysin, and both types of leucocidin) present in culture filtrates. Active immunization with toxoid, but not with vaccines, afforded protection against infection in laboratory animals. There was still difference of opinion about the clinical value of toxoid, antitoxin, and vaccines. The use of toxoid was a rational form of therapy in man, in whom good results had been reported by various workers in some staphylococcal diseases. With regard to chemotherapy, sulphanilamide (*p*-aminobenzenesulphonamide or prontosil album) protected mice against multiple lethal doses (1,000 to 10,000) of highly virulent strains of staphylococcus. As in the case of the haemolytic streptococcus, repeated doses of the drug were necessary to give protection for some weeks. Staphylococci persisted much longer than haemolytic streptococci in the tissues of the protected mice, and might often give rise to abscess formation in the liver and spleen. The results of experiments in mice suggested that sulphanilamide might be of value in the treatment of certain staphylococcal infections in man.

Dr. EILEEN O. BARTLEY (Belfast), whose paper was read by Dr. N. C. GRAHAM (Belfast), reported the results of the therapeutic use of staphylococcus toxoid. A follow-up of a series of cases reported a year before showed a higher proportion of cures than in the original figures. Styes responded best, then boils and dermatitis; sycosis was more resistant. She had titrated the antihaemolysin during treatment, and found an average rise from 1 unit to 7.7, but there was no relation between the degree of this increase and the clinical result.

Dr. S. C. DYKE (Wolverhampton) pointed out that antibody titration only indicated the amount of antihaemolysin formed, and agreed that this was unrelated to the degree of clinical improvement. Autogenous vaccines were sometimes more effective than toxoid: 90 per cent. of cases of recurrent boils could be cured by this means. He denied that diabetics more often contracted staphylococcal infections than other patients, but agreed that these infections were more dangerous when they occurred in diabetics.

Dr. EILEEN M. HICKEY (Belfast) described the successful treatment of a case of generalized staphylococcal infection with prontosil: relapse had followed immediately on the withdrawal of the drug no fewer than five times.

Sir THOMAS HOUSTON said that the original results with vaccines reported by Wright and Douglas were better than those obtained with toxoid. It was important to make an exact bacteriological diagnosis: he had seen cases apparently of pure staphylococcal infection in which in reality there was infection by the enterococcus as well, or by a haemolytic streptococcus. Dr. H. GUY DAIN (Birmingham) pointed out the importance of eradicating other foci of infection; an underlying condition might be a root abscess, and sometimes the antrum was at fault. Colonel A. H. PROCTOR described a study of active immunization carried out at the British Postgraduate Medical School. The anti-haemolysin titre was no criterion of success, and they had also found the bactericidal power of the blood useless as a guide. It was important in severe staphylococcal lesions to guard against secondary infection. Dr. GRAHAM also emphasized the necessity for bacteriological diagnosis; some boils were streptococcal. Dr. A. FELIX expressed his interest in a study which had shown that the phenomena of infection were due to the combined effect of several bacterial antigens.

Professor BIGGER, in reply, said that he believed the different effects of vaccines to be due to the variety of media on which the cocci were grown, and upon which toxin was produced in different amounts. A good toxoid must be derived from alpha and beta toxin and a sufficiency of leucocidin to be effective.

SECTION OF PHARMACOLOGY AND THERAPEUTICS, INCLUDING ANAESTHETICS

Friday, July 23

Anaesthesia in Minor Surgery

With Dr. OLIVE M. ANDERSON (Belfast), a Vice-President, in the chair, Dr. J. H. T. CHALLIS opened a discussion on this subject.

Dr. Challis said that anaesthesia for so-called minor surgical procedures required as much skill and ability on the part of the anaesthetist as did major operations, and that of the various anaesthetic agents available for this purpose no one drug was greatly in advance of the others in respect of efficiency and safety. The ideal anaesthetic for minor surgery should be safe, it should not hinder the patient from continuing his work, the necessary depth of anaesthesia should be available, consciousness should be regained quickly, and the anaesthesia should be pleasant to the patient. Local anaesthesia probably represented the nearest approach to this ideal. The intravenous barbiturates were difficult to use in small children and were contraindicated in the elderly. Nitrous oxide and oxygen was probably the most useful combination for inhalational anaesthesia when the conditions under which minor surgery was conducted in this country were considered. It was an advantage, but not essential, to administer previously a sedative. Dr. Challis recommended the oral administration of an alkaline powder immediately before nasal gas for dental extractions; this seemed to promote a quick and rapid recovery. Vinyl ether had a definite place in minor surgery. Ether was safe, and any required stage of anaesthesia could be secured and maintained. In the speaker's opinion this agent should always be employed for a second surgical intervention in a patient who was exsanguinated and was still bleeding after tonsillectomy. Chloroform was useful, particularly for obstetrical work. Although cyclopropane could not be classified as an entirely safe anaesthetic, it was not without its uses for the purpose under consideration.

Dr. J. H. GILLIES (Edinburgh) said that many anaesthetists were tempted to standardize both apparatus and technique and to apply it to major and minor surgery alike. For the latter purpose local and regional anaesthesia should be used whenever possible, but a keen judgement was desirable for the safe application of intravenous methods. For the enucleation of tonsils by the guillotine he recommended the use of up to 5 c.cm. of ethyl chloride evaporated gradually into a wide-bored Hewitt inhaler through which a trickle of oxygen flowed constantly. There was no cyanosis, but administration should cease as soon as the rapid deep breathing of the third stage of ethyl chloride anaesthesia was evident. For the longer operations of minor surgery, when nitrous-oxide-oxygen and ether, which was the anaesthetic of choice, was not available, the ethyl-chloride-ether sequence was satisfactory.

Dr. W. B. PRIMROSE (Glasgow) said that, notwithstanding the advances made recently in anaesthesia, the production of chloroform was increasing, and he interpreted this as indicating that this agent was being more commonly used for minor surgery. The inhalation of the heavy chloroform vapour involved a physical element of asphyxia which caused deprivation of oxygen, and this in many

cases led to difficulty. The toxicity of chloroform was apt to add its depressing effect and precipitate a collapse. This, however, could be obviated by the use of oxygen. When fully oxygenated, the medullary centres controlled the intake of the drug and automatically adjusted the depth of anaesthesia to the requirements of the surgeon.

Mr. J. S. LOUGHRIDGE (Belfast) said that local anaesthesia, nitrous oxide and oxygen, and sodium evipan were among the safest of anaesthetics. Each had its advantages and disadvantages, but by using two or more agents the advantages of all could be secured and at the same time their disadvantages could be eliminated. He had used a combination of agents, particularly in the simpler acute abdominal emergencies in bad risk cases. The method advocated was to begin the operation under local anaesthesia and to give nitrous oxide or sodium evipan as and when indicated. This method had been used without any apparent distress to the patient in cases of advanced cardiac and pulmonary disease.

Dr. RONALD JARMAN, referring to anaesthesia in children, said that, so far as premedication was concerned, nembutal, in appropriate dosage, could be given by the mouth or paraldehyde or avertin by the rectum. Every child should receive an adequate dose of atropine, and should as far as possible be unconscious of the injection. Nitrous oxide and oxygen, supplemented with ether if necessary, probably constituted the best method of induction, and with a suitable apparatus there should be no difficulty in giving it over any length of time. For dental anaesthesia it was easy to hasten induction with nasal gas and oxygen by spraying 2 or 3 c.cm. of ethyl chloride on to a piece of lint placed in front of the child's mouth. He considered that, for children, intravenous anaesthesia should not be encouraged, for even with some form of premedication the child remained conscious of the prick of the needle and would not forget this. In any circumstances it was essential to gain the confidence of the child. Dr. Jarman illustrated his remarks with a cinematographic film.

Dr. OLIVE ANDERSON asked what type of apparatus was recommended for administering gas and oxygen. There was anxiety in some quarters regarding the employment of heavy premedication in children. Dr. H. A. KELLY pointed out that in practice the anaesthetist has to use apparatus provided by the dentist, and in dental work premedication is usually impracticable. Dr. CECILIA WILLIAMSON (Ipswich), Dr. KATHARINE G. LLOYD-WILLIAMS, Dr. P. M. OVERTON (Bolton), and Dr. MARTHA E. HUTCHINSON (Belfast) raised further points, to which the openers briefly replied.

Vinyl Ether as an Anaesthetic Agent

Dr. VICTOR GOLDMAN, in initiating a discussion upon this subject, based his observations on a series of 1,191 cases in which no death or serious complications had occurred. Anaesthesia was produced with great rapidity; muscular relaxation was complete and similar to that obtained with ethyl ether. There was no irritation of the upper air passages, but there was increased salivation. Mixtures of vinyl ether and ethyl ether were satisfactory, and a mixture of 25 per cent. of the former with 75 per cent. of the latter had been advocated for use by the open method. It had been proved beyond question that this agent had little action upon liver function even when administered to patients with toxaemia of pregnancy. There was no appreciable change in the coagulation time of the blood, and the effect upon the blood sugar compared favourably with that produced by ether and chloroform. Dr. Goldman said that in his hands the administration of vinyl ether by the open method had not proved a success. The extreme volatility of the drug occasioned difficulty in maintaining an even plane of anaesthesia for long cases. For minor surgery he preferred a closed method, and when this was employed for dental work in children he was of the opinion that the results compared most favourably with those obtained with nitrous oxide. For major operations the closed system combining carbon dioxide absorption was the method of choice, and he recommended that the soda-lime canister should be fitted close to the facepiece. Nitrous oxide and oxygen could be bubbled through a small bottle containing 25 c.cm. of vinyl ether and attached to one of the usual forms of gas-oxygen apparatus. There was no contraindication to the use of a basal anaesthetic with vinyl ether, and as an adjuvant to gas and oxygen it had many uses, particularly in order to obtain additional muscular relaxation during an abdominal operation. Dr. Goldman demonstrated his methods with a cinematographic film showing the use of vinyl ether in dental surgery.

Dr. MARY MAYEUR referred to her experiences with vinyl ether in 348 obstetrical cases. The agent was given either by the open method, when it was dissolved in ethyl ether in the proportion of one to three and administered on an open mask of thin gauze, or it was used as an adjunct to nitrous oxide and oxygen. No maternal deaths were observed in the series, no patient stopped breathing or gave cause for any anxiety, and no remote toxic effects were seen. The series included seventeen patients with valvular lesions of the heart, twenty-nine showing signs of severe toxaemia, and two diabetics. Anaesthesia was induced with vinyl ether and oxygen, and in two to three minutes sufficient relaxation was obtained for the obstetrician to insert a hand and perform the desired manipulations. During traction with forceps anaesthesia could be maintained with nitrous oxide, but it was wise to add vinyl ether when the perineum was distended. The action of this drug in not diminishing uterine contractions indicated its suitability as an anaesthetic in the presence of complications in the third stage of labour, but it was not found satisfactory for external rotation where complete relaxation of the abdominal muscles and of the uterus itself were essential. It seemed to combine the advantages of chloroform—namely, rapidity of induction and absence of irritation of the respiratory tract with an undiminished uterine action and a greater margin of safety for the patient.

Dr. G. E. NESBITT (East London, South Africa) inquired the time taken for induction and the period of anaesthesia obtained when vinyl ether was administered by the one-dose method. Dr. JARMAN believed that for obstetrical work nitrous oxide and oxygen was superior to vinyl ether. Anaesthesia could be deepened by the use of an intravenous barbiturate. Dr. OVERTON asked for guidance in the choice of suitable cases for anaesthesia with vinyl ether in major surgery. Dr. LLOYD-WILLIAMS said she was convinced of the value of vinyl ether in obstetrical work.

In reply Dr. GOLDMAN stated that vinyl ether could not replace nitrous oxide and oxygen when this was given by an experienced administrator equipped with adequate apparatus. So far as major surgery was concerned he felt that it should be used only by the anaesthetic specialist. With the single-dose method the induction time was about fifty-five seconds, and the duration of anaesthesia was in the region of one minute.

SECTION OF ANATOMY, PHYSIOLOGY, AND BIOCHEMISTRY

Friday, July 23

Visceral Pain

With Professor HENRY BARCROFT (Belfast), a Vice-President, in the chair, a discussion on visceral pain was opened by Professor JOHN MORLEY (Manchester). The characteristics of pure visceral pain such as originated in the gastro-intestinal tract were that the only adequate stimulus was tension on the afferent nerve endings, that

its localization was vague, and that it was not referred to the surface of the body. On the other hand, pain that was strictly localized and associated with muscular rigidity and tenderness was of somatic origin, and resulted from stimulation of the nerves of the parietal peritoneum. An example was the shoulder-tip pain produced by stimulation of the phrenic nerve terminals below the diaphragm. The mechanism of this pain would seem to be adequately explained by the observations of Barron and Matthews that afferent impulses from the peritoneum entering the posterior root at one segment could be discharged to the periphery at a different segment along collateral fibres. Such "peritoneo-cutaneous radiation" was an example of "referred pain." Testicular pain in renal or ureteric colic and urethral pain due to stimulation of the trigone of the bladder were of this type.

Professor B. A. McSWINEY described experiments on cats that had enabled his colleagues and himself to trace the distribution of visceral afferent fibres in the vagus and splanchnic nerves. The mesenteries of the stomach, duodenum, and ileum were sensitive to traction, and the small intestine was much less sensitive to distension than the stomach and duodenum. There was a very wide segmental distribution of the afferent fibres from any one part of the gastro-intestinal tract. Visceromotor reflexes could be demonstrated by recording action potentials in the rectus abdominis by stimulation of the splanchnics or the peritoneum, traction on the mesenteries, or distension of the pyloric antrum. Painful distension of the stomach or duodenum caused constriction of the finger vessels in man. Referred pain obtained on stimulation of the phrenic nerve was also discussed.

Dr. E. P. POULTON believed that referred pain could come from visceral stimulation, and cited angina and development of a painful spot on the back produced by oesophageal distension. He referred to "reflex" pain such as occurred in the stomach in appendicitis. He discussed experiments performed by Payne and himself on oesophageal distension. The pain thus produced was relieved by the passage of a peristaltic wave, which caused contraction of the muscular walls and therefore relief of the tension on the nerve endings. Successful peristalsis was painless, but a peristaltic wave which failed to overcome an obstruction did not relieve the tension on the nerve endings, and was therefore painful.

Professor J. R. LEARMONTH (Aberdeen) said that the surgeon might be called upon to attempt to relieve visceral pain of two types: (*a*) that accompanying disordered function, and (*b*) pain of a possibly "neuralgic" type. The surgeon was hampered by the lack of intraneural topography in visceral nerves, so that it was impossible to perform neurectomy close to a viscus without disturbing its function. The further from the viscus the more the viscerosensory fibres diverged; and in order to interrupt these diverging sympathetic pathways very extensive operations would be necessary. The speaker illustrated this point by a series of anatomical diagrams. Of available operations there were: division of the superior hypogastric nerve for pain originating in certain pelvic viscera; stripping of the renal pedicle for painful hydronephrosis: division of the thoracic splanchnic nerves for pain in upper abdominal viscera; section or injection of rami communicantes for abdominal and cardiac pain; and cordotomy.

Professor BARCROFT mentioned an observation of Dr. G. W. Theobald that labour pains could be abolished by infiltration of the twelfth dorsal and first lumbar nerves. Professor MORLEY said that the Manchester school had failed to confirm this observation. Professor A. B. APPLETON suggested that the vague localization of true visceral pain referred to by Professor Morley might be due to the wide segmental distribution of the afferent nerves.

Professor MORLEY, in his reply, said that the real field for the investigation of visceral pain was the human body, and that it was difficult accurately to detect pain in animals. Professor McSwiney had described visceromotor reflexes from the pylorus, but the speaker had yet to see evidence in abdominal disease of viscerosomatic reflexes occurring as the result of painful stimulation of abdominal viscera. In regard to Dr. Poulton's experiments, he wondered how far the oesophageal tension might stimulate adjacent somatic nerves and thus produce the referred pain.

Afferent Nerve Supply of Arteries

Dr. J. DIXON BOYD (Cambridge) read a paper on the afferent nerve supply of arteries, with special reference to pressor-receptors. Approaching the subject from the embryological aspect, he traced the development of the branchial arch arterial system and its afferent nerve supply. He suggested that the sudden closure of the ductus arteriosus at birth was maintained by the pressor-receptor nerve fibres with which its walls were plentifully supplied. It was possible that the cells of the carotid body were chemoreceptor and sensitive to changes in the blood composition of the respiratory gases. Similar collections of epithelioid cells were to be found in the neighbourhood of the arch of the aorta, the ductus arteriosus, and the pulmonary artery, the last-named being sensitive to changes in the composition of the venous blood.

Vascular Reactions of the Kidney

Dr. D. H. SMYTH (Göttingen and Belfast) read a paper on vascular reactions of the kidney in response to carotid sinus and other reflexes. It was found that the kidney possessed an automatic mechanism of vascular control and that its blood flow remained relatively unaffected by general vascular reflexes designed to redistribute the blood supply of the body as a whole, such as could be initiated by stimulation of the carotid sinus, clamping the carotid arteries or aorta above the renal arteries, or the administration of adrenaline. The response of the renal blood flow to these manœuvres was very slight, and was unaffected by denervation of the kidney.

Dr. J. S. LOUGHRIDGE (Belfast) asked if the effect of pituitrin on the blood flow through the kidney had been investigated, and Dr. SMYTH replied that he had not done so. Professor BARCROFT asked if there was any evidence as to the function of the cells of the carotid body. Dr. BOYD replied that the nerve endings in the carotid body appeared to be sensory, but the cells themselves seemed to be secretory, and suggested that the carotid body might bear the same relation to a parasympathetic ganglion as the adrenal medulla bore to a sympathetic ganglion. He pointed out that one would expect such vital organs as the brain, the heart, and the kidney to be independent of the general vascular reflexes of the body, and in response to his question Dr. SMYTH stated that the renal experiments had been repeated on the coronary vessels with similar results.

Chemical Mediators in Nervous Activity

Professor T. H. MILROY (Edinburgh) read a paper on chemical mediators in nervous activity, in which he dealt with the electrolytic changes that took place at phase boundaries such as might be caused by the liberation of acetylcholine at a synaptic junction. Acetylcholine was actually adsorbed on to the membrane and altered the change of the electrostatically fixed layer, where it acted as a cation by neutralizing some of the electronegative ions. The potential at the phase boundary was therefore altered, and this gave rise to the action currents, which could be demonstrated.

Physiology and Biochemistry of Diseases of Muscle

Dr. S. NEVIN read a paper on the applications of advances in physiology and biochemistry to the study of diseases of muscle. He confined himself to a description of electromyographic studies of cases of myotonia, con-

sisting of action current records and pressure tracings from balloons held in the hand and placed over the muscles of the forearm. The clinical features of myotonia consisted of a pathological delay in relaxation of muscles after voluntary contraction, seen particularly in hand-grasping, and aggravated by cold and relieved by warmth. The electrical records showed an outburst of high-frequency action current discharges, both in the flexors and in the extensors, during the period of relaxation. It would appear that there was an increased sensitivity of the end-plate, leading to abnormal resumption of postural tonic impulses.

SECTION OF DISEASES OF CHILDREN

Friday, July 23

Enuresis

With Dr. ROBERT MARSHALL (Belfast), Vice-President, in the chair, a discussion on "enuresis" was opened by Dr. ROBERT HUTCHISON, whose paper was published in the *Journal* of July 31 (p. 206).

Dr. STANLEY GRAHAM (Glasgow), dealing with biochemical considerations, pointed out that the exclusion of organic disease was of great importance, since enuresis might be a symptom of a pyogenic infection of the urinary tract. Pus cells seen in a drop of uncentrifugalized urine and the growth of organisms in culture indicated the diagnosis. When enuresis began for the first time about the age of 4 or 5 years, especially in girls, a pyogenic infection was found in the majority of cases. Adequate treatment of such infection along modern lines yielded satisfactory results, and the question of some congenital malformation of the urinary tract had to be considered if such treatment failed. Chronic interstitial nephritis or renal dwarfism, continued Dr. Graham, was another condition in which bed-wetting might be a leading symptom, usually associated with thirst. Evidence of renal failure was obtained in such cases by examination of the blood for nitrogen retention. Dr. Graham also mentioned diabetes mellitus and diabetes insipidus as causes of enuresis. He was not convinced that spina bifida occulta was a cause of enuresis, but stone in the bladder and acute nephritis had certainly to be considered. As regards treatment, when organic disease had been excluded Dr. Graham thought that the greatest hope lay in the development of psychological measures.

The CHAIRMAN asked about the management of the persistent occasional enuretic who only had a wet bed now and then. He wondered if such occasional lapses had anything in common with the occasional-fit type of epilepsy. He thought that mothers of enuretic children were either too fussy or too careless. Dr. H. MORLEY FLETCHER (President) stressed the importance of early training of infants in control of the bladder, stating that a child of 1 year old ought to be dry by day. No cure of nocturnal enuresis was possible until a child was controlling his bladder properly in the daytime. He also mentioned the type of nocturnal incontinence which developed at puberty, and the occurrence of enuresis after one of the acute specific fevers.

Dr. E. A. BENNET emphasized the psychological aspect of the subject, stating that it was very important to consider the parents and the whole environmental situation of the child. He said that an enuretic child must be made to take the responsibility for the condition, and he had found it useful for such a child to keep a diary of his progress under treatment. Dr. R. E. STEEN (Dublin) agreed as to the importance of the psychological aspect of the subject. The child required help and not blame for its condition. He mentioned the importance of cutting down the food intake as well as the fluid in the second part of the day. Dr. W. R. F. COLLIS (Dublin) was also glad that the psychological aspect had been stressed. In the majority of cases of enuresis he thought there was some conflict in the home. Professor SEYMOUR BARLING (Birmingham) stressed the complicated nature of the function of micturition and the necessity for careful training in the transition stage, when control of the bladder was being gained.

Dr. KATHLEEN MCKEOWN asked about the child coming from a poor home who had received no sort of training at all. The enuresis was sometimes discovered for the first time only when the question of a convalescent home was raised. She asked how long psychological treatment might be expected to take. Dr. T. H. CROZIER (Belfast) agreed that the greatest difficulty was often seen with the hospital patient who shared a bed with several others. Dr. D. C. R. R. JENKINS (Belfast) spoke of his difficulties as medical officer of a public school, particularly when boys wet the bed there and not at home. He had noticed excessive acidity of the urine in some cases.

Tuberculous Cervical Adenitis

Professor BARLING, in a paper on this subject, dealt especially with the modern tendencies in the treatment of the disorder. Tuberculosis of the glands in the neck was, he said, usually a focal infection originating in the oral and nasal tissues, the tonsil being by far the most frequent source of such infection. The disease was uncommon under 2 years of age, and the majority occurred in childhood and adolescence. He thought the disease essentially resulted from low dosage and limited local infection. Diagnosis was often difficult in the early stages, and might account for fallacies as to the efficacy of non-operative measures of treatment. In early cases treatment by the mercury-vapour lamp was to be recommended, especially in the younger patients with a recent infection. Surgical excision was indicated if there was any extensive breaking down of the involved glands, and also if discrete glands or masses of some size remained after a suitable course of non-operative treatment. Professor Barling emphasized, in conclusion, that operations in tuberculous adenitis called for surgery of a high order. Dr. HUTCHISON said that as a physician he saw such cases, and he was struck by the extreme frequency of the association with septic tonsils. He thought that the use of sunlight and other measures were uncertain and time-consuming compared with surgical excision. Professor JOHN MORLEY (Manchester) agreed that the reaction against surgical procedures had probably gone too far.

Thyroid for Premature Babies

Dr. ALAN MONCRIEFF explained that the method of stimulating premature babies by means of thyroid extract had been introduced by Dr. Eric Pritchard, although clearly deriving from the classical experiments of speeding up the development of tadpoles by use of this substance. He gave the results of a controlled experiment at Queen Charlotte's Hospital by which it was shown that the mortality rate among premature babies not receiving thyroid was over three times that among such babies who were given 1/20 grain of thyroid extract daily per pound of body weight during the early days of life. Dr. COLLIS confirmed the value of this method, and mentioned its use in preventing low temperatures in premature babies.

SECTION OF NUTRITION

Friday, July 23

Physiological Bases and Standards

With the President, Sir ROBERT MCCARRISON, in the chair, Professor STUART J. COWELL opened a discussion on the physiological bases and standards of nutrition.

Professor Cowell said that although with further advances in knowledge most of the diseased states now recognized might be definable in terms of definite disturbances of metabolism or nutrition, it would be convenient to limit the sphere of the discussion to those nutritional processes which are known to be more or less

directly related to the intake or absorption of food. He would confine his observations, as the report of the Health Department of the League of Nations had done, to practical questions such as what we could hope to accomplish by dietary recommendations and what diets were most likely to secure the desired effect. The experience of most of those engaged in controlled feeding experiments with laboratory animals had been that diets which promoted the most rapid growth in early life maintained the animals in the most vigorous health in adult life. The question of the maintenance of a state of health and full vigour was becoming more and more widely recognized as one in which right feeding must occupy a prominent position. Frank deficiency diseases due to a low intake of mineral elements and vitamins, and possibly of good protein, were by no means rarities in the British Isles. How far minor degrees of specific deficiencies were responsible for lessened vigour and vitality and lowered resistance to infections and degenerative diseases was a matter of conjecture, but steps were being taken to fill in this gap in our knowledge. Professor Cowell declared that it should be possible to reduce enormously the amount of dental decay in the next generation by securing as perfect a state of nutrition from the pre-natal period onwards as existing knowledge would permit. He regretted the tendency in some quarters to assume that an adequate supply of essential food constituents was that which prevented the appearance of gross signs of deficiency diseases, whereas there was evidence that improved states of nutrition could be secured by increasing the intake to a liberal extent above the protective level. The practical steps he recommended were the provision for everyone of liberal quantities of the protective foods. This could most easily be achieved by increasing the consumption of safe milk and dairy products, green vegetables, eggs, fat fish, and liver, with a corresponding decrease in the consumption of refined sugar and cereals. The essence of the scheme for securing good nutrition in children was insistence on a high proportion of the protective foods. Between the ages of 1 and 3 three-quarters of the calories should be obtained from protective foods, and between the ages of 3 and 7 about two-thirds.

Dr. HELEN M. M. MACKAY dealt with standards of iron nutrition, considering iron deficiency as an example of a condition in which departures from normal were measurable as a result of the establishment of normal standards of haemoglobin level for the adult and for the young child. She pointed out that the existence of these standards had brought to light the fact that iron deficiency was perhaps one of the most widespread deficiencies in human diets. She made a plea for the earlier introduction of mixed feeding in infant work.

Dr. J. F. BROCK (Cambridge) dealt with the question of those people for whom average dietary standards were not adequate. He reviewed the various mechanisms by which disorders of the gastro-intestinal tract could condition deficiency disease in people whose dietary intake was inadequate by ordinary standards. Some of these disorders were apparent at once, but of greater interest were those in which there were no symptoms of gastro-intestinal disorder and the general state of nutrition of the patient was good. He instanced Addisonian anaemia as an example, and stated that recent research suggested that silent disorders of the stomach and intestine were commoner than had been apparent in the past. He referred to examples of interference by one dietary constituent with the absorption of another, and suggested that the remedy was to insist that supplements of concentrated or synthetic vitamins or of medicinal preparations of mineral elements should always be an addition to and not a substitute for a diet which was adequate in every respect in dietary constituents derived from natural foods. He reinforced the opener's plea for liberal rather than minimum nutritional standards.

Dr. J. C. SPENCE (Newcastle-upon-Tyne) quoted instances to support the thesis that conditioned deficiency disease was very common in the practice of medicine. He stressed the importance of individual variation in dietary requirement. Important sources of deficiency states were latent steatorrhoea and gastro-enterostomy. The physiology of appetite had been very imperfectly studied.

Professor W. R. FEARON (Dublin) read a paper on the metallic microconstituents of a modern diet. He said that the number of microconstituents necessary for life was between 40 and 60. He outlined the role of certain of them, especially copper, zinc, and cobalt. Cobalt deficiency disorders had recently been described in Australian sheep. He dealt with the marked differences between brown and white bread in respect to the content of microconstituents.

A paper on the detection of malnutrition, by Dr. W. R. AYKROYD (Coonor, India), was read for him by Professor D. C. HARRISON. His remarks were concerned with the state of nutrition of children in Southern India, where the diet was almost universally defective by Western standards. Marked differences between height and physique as between rice-eating and tapioca-eating communities could be related to diet rather than to race. The incidence of angular stomatitis, xerophthalmia, and follicular keratosis, together with certain anthropometric measurements, had been related to states of nutrition.

Food Intakes and Requirements

Dr. R. A. MCCANCE read a short paper on food intakes and food requirements. Minimum requirements could be fairly accurately estimated, but the margin between that and optimum requirements always varied with the judgement of the observer. He pointed out certain fallacies in the method of calculating family requirements and intakes and their reduction to man-value equivalents, and recommended the measurement of individual food intakes. Professor W. A. OSBORNE (Melbourne, Victoria) pointed out the cheapness of food in Australia. Milk, however, was scarce in the metropolitan areas, and green vegetables scarce in the areas of low rainfall. Although the evidence that malnutrition led to imperfect teeth was incontrovertible, the reverse assumption that imperfect teeth were due to malnutrition was false. Dr. J. H. STRAHAN (Singapore) had found caloric man values well below 2,000 in certain parts of Malaya. Vitamin deficiencies were commonly encountered. Dr. LUCY WILLS had found that B_1 deficiency became manifest in her animals when the metabolism was increased by the rectification of other deficiencies. Dr. S. MILLER (Harrogate) said that by persistent iron therapy he had been able to raise the haemoglobins above the usually accepted normal levels.

SECTION OF OPHTHALMOLOGY

Friday, July 23

Affections of the Eye with Relation to Skin Diseases

With the President, Mr. J. A. CRAIG (Belfast), and subsequently Mr. J. D. M. CARDELL in the chair, Mr. J. H. DOGGART and Dr. G. B. DOWLING opened a discussion on affections of the eye with relation to skin diseases.

Mr. Doggart, speaking from the ophthalmological aspect, drew attention to the great degree of overlapping between the dermatologist and the oculist on purely anatomical grounds. He said that there was, however, a deeper common interest in that ocular treatment may sometimes have to be materially modified owing to the state of the adjacent skin, and in that the eye may have to be protected from remedies applied to the upper part of the facial skin. One characteristic of the skin of the eyelids was its great tendency to oedema, as seen in inflammatory lesions and in such traumatic conditions as the "black eye." A condition of particular interest was blepharochalasis, since this represented the result of

repeated attacks of distension of the skin of the lids. A whole group of new skin irritants, particularly active in the case of the lids, had come with synthetic chemistry; some of the new compounds cause direct local irritation, others, like orris root in shampoos, excite an allergic reaction. The work of Ridley had shown the allergic nature of atropine irritation, and a point of significance was the extreme rarity of atropine intolerance in the absence of some congestive disease of the eye. Blepharitis was frequently part of a general skin condition such as seborrhoea, pityriasis, or sycosis. In the treatment of blepharitis the avoidance of chronic dermatitis in the adjacent skin was important, as otherwise a vicious circle was apt to be set up. Strong chemicals were to be deprecated in the treatment of blepharitis. Mr. Doggart referred to the encouraging results that had been obtained in styes by the use of autogenous vaccines, but in many cases no local infection or existing cause can be established. Corneal lesions had to be regarded as lesions in ectodermal tissues which share the susceptibility of the skin to certain infections and dystrophies. Myxoedema, measles, pemphigus, and dermatitis herpetiformis all illustrate that tendency, whilst the corneal lesion of acne rosacea illustrated a type that was well ground into the consciousness of ophthalmologists. Rosacea keratitis, in particular, was the type of lesion that had to be treated on general lines, and too energetic local treatment avoided.

Dr. DOWLING, speaking as a dermatologist, said that rosacea was to be regarded primarily as a vascular disturbance, becoming troublesome later in life. Gastric disorders were contributory factors only, whilst the menopause with its vasomotor disturbances was not to be ignored. Ocular complications appeared most commonly in the constitutional hereditary type of vasomotor rosacea, and infection played little or no part in it. Drawing a distinction between seborrhoea and dandruff, he classified blepharitis as seborrhoeic and as the result of sycosis of the eyelashes; the first might be complicated by infection, whilst the second was frankly infective. Dermatitis of the eyelids had also a multiple aetiology; infection, chemical irritation, and seborrhoea, in addition to unknown factors, were to be considered in this affection, which begins with an acute attack and tends to become chronic. Rubbing to allay irritation aggravates the condition, and local treatment was difficult. Turning to less common conditions, he discussed lupus, basal-celled epithelioma, pemphigus, warts, and xanthelasma in their bearing on ophthalmology.

In the discussion that followed Mr. J. D. M. CARDELL referred to the gravity of lid involvement in leprosy, a view which was not shared by Lieut.-Colonel R. E. WRIGHT, who emphasized the seriousness of herpes ophthalmicus. Mr. G. G. PENMAN drew attention to the danger of corneal perforation in rosacea keratitis. Mr. R. AFFLECK GREEVES regarded some forms of blepharitis as symptomatic of infection of the meibomian glands. Such infection was also taken as a factor in rosacea keratitis by Mr. E. J. PRIMROSE (Glasgow). Dr. H. MACCORMAC emphasized gastro-intestinal dysfunction rather than vasomotor disturbances in rosacea.

Glaucoma Secondary to Injury

Mr. R. AFFLECK GREEVES read a paper on some unusual cases of glaucoma secondary to injury. He cited four cases, in two of which glaucoma developed after a non-perforating injury; in none of them were any of the usual causes of secondary glaucoma present. In the first case the eye was trephined, the operation being followed by papilloedema and ultimate peripheral constriction of the field, with retinal vascular changes but permanent normal intra-ocular tension. In the last two cases glaucoma developed as the result of the retention of an intra-ocular foreign body, the existence of which had been unsuspected by the patients themselves. In the first case the foreign body proved to be magnetic, and after its removal by operation the tension remained normal. In the second case the foreign body was non-magnetic, and its removal was not possible. By means of a trephining operation normal intra-ocular tension was obtained, the foreign body remaining *in situ*.

The possible aetiology of the glaucoma in these cases was discussed by the PRESIDENT, Mr. CARDELL, and Mr. W. B. INGLIS POLLOCK (Glasgow).

Corneal Transplantation in an Aphakic Eye

Mr. J. V. MCAREVEY (Dublin) followed with a paper on corneal transplantation in an aphakic eye. After pointing out the value of infra-red photography for examining the state of the pupil, the presence of anterior synechiae and the existence of defects in the iris, and stressing the help that could be obtained from double transillumination with the slit-lamp, he gave an account of a patient with bilateral leucoma and cataract on whom he had performed keratoplasty. In the case of the first eye the graft, which had been clear, became opaque; later, tension developed, the graft burst open, and the opaque lens became extruded, ultimately leaving perception of light only. When operating on the second eye the graft was placed eccentrically so as to avoid synechia. The result was better than with the first eye, though the initial conditions had been less promising. The speaker thought it was best not to attempt cataract extraction at the time the corneal grafting was done.

The PRESIDENT congratulated Mr. McArevey on his successful use of infra-red photography, and Lieut.-Colonel WRIGHT discussed the significance of slit-lamp examination, as well as points in the technique of the operation.

Colour of the Optic Disk

Mr. EUGENE WOLFF, in a paper on the colour of the optic disk, drew attention to the great number of small vessels normally present at the nerve head. This helped to explain not only the normal colour but the presence of oedema at the disk in such lesions as renal retinitis. The temporal part of the disk contained a thinner layer of nerve fibres and fewer capillaries than the nasal part. This accounted for the normally whiter appearance of the outer half of the disk, and for the relatively ill-defined nasal edge. Nerve fibres are crowded together most at the disk edge of the upper and lower inner quadrants, a fact which explained the localization of the first signs of swelling of the disk. The white element in the colour of the disk was due to the lamina cribosa and to the medullated nerve fibres behind it. The whiteness becomes exaggerated in primary optic atrophy owing to the disappearance of capillaries and nerve fibres obscuring the lamina cribrosa. The white colour is less marked normally in the baby, and in the newborn the disk appears grey. Two factors entered into this modification: myelination of the optic nerve fibres (with the white appearance it carries) does not reach the lamina cribrosa till after birth, and the lamina itself is almost transparent at birth, becoming more opaque and white with time. The paper was illustrated with histological preparations and photomicrographs.

SECTION OF ORTHOPAEDICS

Friday, July 23

Treatment of Club-foot

With the President, Mr. S. T. IRWIN, in the chair, Mr. DENIS BROWNE opened a discussion on modern methods of treatment of club-foot. The speaker gave a brief account of the observations that had led to the formulation of his theory, the revival of one put forward centuries ago, that club-foot and many other congenital deformities such as spina bifida and arthrogryposis multiplexa congenita were the result of increased intrauterine pressure. Most convincing photographs of newborn children showed how these deformities might easily have been produced *in utero*, the chief pressure points being revealed by deep

and permanent dimpling of the skin. Treatment of the early case consisted in vigorous manipulation of the feet and the application of the splints designed by the speaker.

Mr. E. P. BROCKMAN concerned himself chiefly with treatment. He had abandoned strapping and plaster-of-Paris in favour of the Denis Browne splint, and was certain that his results were now better than formerly. The great advantage of the splint was that it allowed the child to use the leg muscles; not only did this prevent atrophy but the child corrected the equinus deformity by kicking, the forefoot alone meeting the resistance of the splint. Yet in spite of thoroughly efficient early treatment a number of cases remained incompletely corrected, or relapsed after apparently successful correction. For these, open division of the soft parts on the medial side of the tarsus (methods described by Ober, Elmslie, and Brockman) was recommended. Unfortunately this procedure was often followed by relapse. In the end a bone operation might be required, and a triple arthrodesis on the lines suggested by Lambrinudi was probably the best of these last-resort methods.

Mr. T. P. MCMURRAY (Liverpool) maintained that early, thorough, and prolonged treatment would almost always yield satisfactory results. If "over-correction" could be obtained, so that the child could easily hold its foot in a position of calcaneo-valgus, then relapse need not be feared. The stiffness and atrophy following fixation in plaster were not permanent, and there was nothing against the use of plaster if properly applied. In badly treated cases, where manipulation failed to give complete correction, open operation was necessary; but inasmuch as the deformity was bony, the soft-tissue operation could not be expected, as Mr. Brockman had admitted, to give a reasonable prospect of permanent correction, and some form of bone resection would be required sooner or later.

Mr. R. C. ELMSLIE congratulated Mr. Denis Browne both on his ingenious theory of the origin of club-foot and on the efficacy of his splint, which was probably the greatest contribution to the treatment of club-foot during the last twenty-five years. In a way, it was a return to the methods of the nineteenth century orthopaedic surgeons, who corrected the deformity gradually with instruments such as Scarpa's shoe, and whose results were probably better than those of present-day practice. He felt sure that surgeons to-day were too impatient and too prone to resort to open corrections. There were, no doubt, cases in which open operation was inevitable, and he agreed with Mr. Brockman's views on this type of treatment. The soft-tissue operation dated from Rushton Parker and wedge tarsectomy from Walsham, both working in the last quarter of the nineteenth century. Since their time nothing beyond minor refinements had been added.

Mr. H. O. CLARKE (Manchester) had hoped that the openers would produce statistics to give clear definition to their statements. If this were really a discussion on modern treatment, it should have been possible to say how many cases would resist manipulative treatment, how frequently the soft-tissue operation was successful, and so on. The discussion was continued by Mr. ERIC LLOYD, Mr. H. F. MACAULEY (Dublin), Mr. V. J. M. TAYLOR (Nottingham), Mr. IAN FRASER (Belfast), Mr. H. J. SEDDON, and the PRESIDENT.

In reply, Mr. DENIS BROWNE said, in answer to a question, that although disturbance of intra-amniotic conditions was difficult to demonstrate, there was no doubt that abnormal enlargement of the uterus had been noted in a number of cases (hydramnics) and curious pains late in pregnancy (oligohydramnios—or perhaps increased tension in an amniotic sac of normal size) in others. A comparable condition was well known in sheep.

Treatment of Tennis Elbow

A discussion on the treatment of tennis elbow was opened by Mr. G. P. MILLS (Birmingham), whose paper appeared in the *Journal* of July 31 (p. 212).

Mr. K. H. PRIDIE (Bristol) had seen a number of cases in which a tennis elbow was only one result of persistent muscle imbalance—in other words, bad play. There was often an associated stiffness of the neck, which called for treatment just as much as the elbow. Mr. W. E. TUCKER considered that there were three varieties of tennis elbow, one due to a partial tear at the origin of the extensor carpi radialis brevior, another—difficult to cure—due to an epicondylar bursitis, and one resulting from a fibrositic deposit in the olecranon fossa. In his experience general anaesthesia was not always essential for the performance of the manipulation.

Mr. ELMSLIE was surprised that no one had considered the question of focal sepsis. He himself had suffered from a tennis elbow (as a result of manipulating club-feet!), which did not clear up until an infected wisdom tooth had been removed. Mr. D. MCVICKER (Belfast) thought that the lesion was almost always intra-articular.

Professor E. W. HEY GROVES (Bristol) had dealt chiefly with intractable cases, and most of them seemed to belong to the "muscle-tear" group. He had found it useful, as a diagnostic measure, to inject the painful area with novocain. If the pain disappeared completely the diagnosis was confirmed. For the intractable case he recommended freeing the extensor mass at its origin through a small incision. Mr. G. K. MCKEE had seen many relapses after manipulation. In these difficult cases he, too, favoured open operation, and had found on several occasions a well-defined area of oedema at the origin of the extensor muscles. Mr. F. CROOKS (Nottingham) found that nine-tenths of his cases were of the muscle-tear type, and he treated them exactly as he would any other muscle tear—namely, by rest. Two weeks was generally sufficient, followed by gradually increasing active exercise. In the PRESIDENT'S experience the injury producing a tennis elbow was often trivial and out of proportion with the disability that resulted. He believed that the lesion was essentially a tear at the origin of the extensor muscles, frequently followed by a traumatic periostitis. This explained the intractability of the pain in many cases.

Mr. MILLS, in reply, said that while some cases were undoubtedly due to a muscle tear there was no denying that the lesion must be intra-articular in most cases. How else could one explain the limitation of extension, the sensation of something being "out" in the joint, and the sudden recurrence of symptoms following an incautious movement a week or two, perhaps, after a successful manipulation?

Mr. TUCKER read a short paper on athletic injuries to the knee, excluding damaged cartilage.

Health Legislation in Industry

The President (Dr. THOMAS CARNWATH) said that the discussion was appropriate in view of the new Factories Act. Legislation was the framework within which the industrial life of the nation must be carried on, but it was important that it should be neither too rigid nor too elastic, and that the contribution of medical knowledge to the wider realization of a well-ordered society should not be disregarded.

Dr. L. P. LOCKHART (Nottingham), in an opening paper, said that medicine in one way or another was coming into more intimate contact with industry. The Factories Act had brought the possibility of medical supervision on a wide scale into practical affairs. The selection of staff, the training of supervisors, and the investigation of production problems had medical implications. An industrial training for doctors as a postgraduate course with practical experience was essential; merely to visit industries

was quite inadequate, and the proper training took time. In addition to a study of processes some insight into managerial functions and technique was necessary to enable the doctor to understand the problems of administration. Industry was beginning to take medicine into its counsels and give it more than a purely research and supervisory function. A step in the right direction was taken when the Representative Body at the Belfast Meeting had approved an ethical code for doctors working in industry. The Council of the Association also, in order to deal with the wider issues of social medicine, had formed a joint committee with the Trades Union Council. The Factories Act laid considerable burdens on the profession, and the necessary machinery to train and educate doctors for industrial work had to be evolved. Medicine was becoming a function of management.

The Small Factories

Mr. J. E. WILSON (Belfast) said that while many of the great industrial undertakings had their own medical service, there were about 124,000 factories in Great Britain and Northern Ireland in which fewer than 250 persons were employed, and in factories employing between 100 and 250 persons there were about 21.5 per cent. of the total number of workpeople, as against only 16.3 per cent. in factories of 1,000 and upwards. It was in this field that the need for a trained industrial medical service was urgent. He looked for a useful result in this connexion from the establishment of the new Department of Industrial Medicine by the University of Birmingham. Many of the smaller factories would welcome the opportunity to secure the part-time service and co-operation of a fully trained medical officer where a whole-time officer would not be justifiable, and such a man could supervise several small factories. Mr. Wilson mentioned that the first reference he could find to a works doctor was in 1830, when a worsted spinner advised that a medical officer should visit his works daily and watch the effect of the work on the children's health. There were also records of a John Smith of Deanston, near Stirling, who in 1842 retained the services of a "medical gentleman" to inspect the workpeople from time to time. More than fifty years later the various voluntary efforts were recognized by the appointment of Dr. Thomas Legge as the first medical inspector of the Home Office.

A Co-ordinated Service

Mr. ERNEST BEVIN (chairman, Trades Union General Council) said that with the passing of the Factories Act and the placing of the industrial health problem on a more organized basis an opportunity presented itself for a really co-ordinated service which for the first time could be made universal in its application. It had been assumed for a long time that the main thing to be looked for in a case of illness was whether or not the worker was a malingerer. Practically the whole of the laws relating to workmen's compensation and the restrictions associated with certain health services had been based on the supposed necessity for protection against exploitation on the part of the worker. Happily, with the growth of the study of psychology and a deeper understanding of the industrial health problem, this approach to the subject had been changed. Another difficulty was the attitude of the people themselves to the works doctor, who was looked upon as a person employed by the management to protect its interests. Mr. Bevin was hopeful that before long the new joint committee of the B.M.A. and the T.U.C. would examine the whole problem with a view to ascertaining the best possible way of establishing, not a new segregated, but a co-ordinated medical service, with a comprehensive research organization. Taking the great hospitals as centres, what he desired to see was an experiment whereby twenty or thirty insurance practitioners might pool the whole of their insured patients, the State or public authorities providing the necessary building accommodation and equipment for the setting up of a special clinic. Each of those participating, whilst continuing as a general practitioner, would have the opportunity to specialize on some phase of industrial medical work, and works doctors would take part in the work of the clinic, acting as part of the general practitioner service. There should be close contact between such clinics and the hospitals and research institutions, and every possible facility should be given for the carrying out of such work.

Dr. R. E. LANE (Salford), after citing the electric accumulator industry during the last twenty years as affording a concrete example of what could be done to safeguard health in a dangerous industry, spoke of the need for the availability of expert medical advice for the employer on request. Where experimental work was necessary resort might now be had to London or Birmingham University, where a Department of Industrial Hygiene had been opened. In other instances the problem might be investigated by the Industrial Health Research Board.

Irish Experience

Major GRAHAM SHILLINGTON (Minister of Labour) and Mr. J. M. ANDREWS (Minister of Finance) made a few complimentary remarks, the former saying that in social legislation Northern Ireland endeavoured to keep on parallel lines with Great Britain.

Mr. W. J. MCCAGHEY (Chief Inspector of Factories, Northern Ireland) spoke of the great improvement in factory conditions which had taken place during the forty years of his own experience. In the linen industry the ventilating and humidifying plants in most of the factories had recently been completely renewed or overhauled. The small, struggling employer presented the real problem, but he must not be permitted to retard progress. Improved conditions of work were becoming more urgently necessary because of the increasing monotony and continual speeding up in these days of mass production and mechanization. It was common ground that many occupations had injurious effects on the physical condition of those engaged in them. The employer and his managing staff could not be expected to detect signs of physical trouble among the workers. Only a trained medical man could do this, and it was therefore vitally important that the medical profession should become more acquainted with occupational diseases. The factory inspector would always welcome the works doctor and regard him as a collaborator.

Economic Considerations

Sir FRANCIS FREMANTLE, M.P., said that the real difficulty was the small business. How could a Belfast employer whose handkerchiefs cost 1s. 4d. a dozen to make compete with Japanese imports at 7½d. a dozen, still less spend money on improving his buildings or conditions of labour? Industry was also up against the appalling prospect of a declining population, with an increasing number of aged persons to be supported. The main hope was not through standardized legislation, sympathetically administered as it was by the able inspectorate of the Home Office, but by the drawing together of employers and employed and of their organizations. In this task the medical profession must play a leading part. The medical student, however, was not trained for this purpose; he was trained for the treatment of disease and not its avoidance in the individual or in the mass. A fundamental reform of medical education, based on the application of physiology to the individual and national life at large, was essential for the future of industrial health. Mr. MCADAM ECCLES said that he felt history had been made in that Section. He mentioned particularly the new conditions to which the introduction of the petrol engine had given rise. In this field both accident and disease might be dependent upon strain, and a continuance of both mental and physical fitness was essential for their avoidance. It was for the medical profession to realize the causes, effects, and methods of prevention and alleviation of strain, and particularly to diagnose strain in the early stages.

Disabilities Industrial and Non-industrial

Dr. J. F. BRAILSFORD (Birmingham) referred to the difficulty of establishing the effect which industry had had in the causation of a particular disability. Often it happened that disability did not arise until years after the first exposure to risk. He frequently came upon isolated cases in which the condition, although giving rise to suspicion, could not be fastened upon any industry. A marble worker, for example, might be found to have fibrosis of the lungs, and yet it was very difficult to establish industrial silicosis as a factor.

Dr. LEONARD KIDD (Enniskillen) mentioned that Northern Ireland was in the rather unenviable position of being the only self-governing Dominion which had not a Ministry of Health. He failed to see how full justice could be done to the workers without such a Ministry. Dr. H. C. SMITH (London) said that among his insured patients were a number of garage employees, and over a period of eighteen months or two years he had seen fit and healthy young fellows become gradually more neurotic and get gastric and other troubles "which should belong to men of seventy." Some of these men feared that if they "went sick" they would possibly lose their jobs, even though they had been working on them for fifteen or twenty years, and this fear reacted prejudicially on their condition.

Dr. H. E. COLLIER (Reader in Industrial Hygiene, Birmingham University) pointed out that the one purpose of industrial hygiene and medicine was to study the industrial factor in the production of disease and the creation of health. The Department at Birmingham with which he was associated hoped to be able to play a part in the industrial medical education of that large body of medical men and women who were urgently needed to-day to help to recognize the industrial factor in health and disease. Many types of practitioners would be required for the new health service for industry. A few whole-time specialists would be necessary, as well as a large number of part-time industrial medical men and women, but there must also be a much larger number of general practitioners working in industrial areas and possessed of an accurate knowledge of the conditions obtaining therein. Such practitioners would be able to recognize deviations from health and take part in industrial medical research.

Colonel A. B. MITCHELL stressed the need for impartiality in the medical examiner called upon to pronounce on industrial disease. In his own experience as an examiner he could not recall an employer who had ever expected him to give an opinion other than the one he had honestly formed. Dr. J. S. MORROW (Belfast) mentioned the difficulty of ensuring that workmen took ordinary hygienic measures—for example, in the case of plumbers working with lead, that they washed their hands before taking a meal. Dr. W. PATERSON (Willesden) agreed with Mr. Bevin as to the necessity for sympathy in examining an employee or candidate for employment. In the factory in which he was a medical officer he was on such good terms with the men that he could ask them such questions as what time they went to bed and whether their wives were good cooks. He never rejected a candidate right away, always suggesting to him that if he saw his doctor and received treatment he might be fit for the job for which he was applying. He welcomed the new provision whereby young people under 16 would come into national health insurance. There had been a tendency for young persons of that age to forego a visit to the doctor because they knew that if they waited until they were insured they could get the doctor's services for nothing. These young people ought to be got into the habit of consulting their family doctor on every occasion. The doctor who laughed at a person who came along with a trivial ailment did not know his job. Municipal clinics did excellent work, but they did tend to break the habit of going to the family doctor. The insurance practitioner ought to be the medical officer for the smaller factories, though he might not have an official appointment.

Replies to Discussion

Dr. LOCKHART, in reply, said that industrial doctors did not want to remain in isolation. When there came a chance of joining in with other people no one would be more willing than they. Mr. BEVIN said that there need be no fear that an industrial medical service was going to ruin industry. That was contrary to the experience of all industrial history. One of the great difficulties in getting the insurance practitioner into part-time industrial service was the fear of other insurance practitioners that he would steal their patients. The only way to get over it was by co-operation, and the medical profession had grown up on individualism. The B.M.A. would fight against a rigid State medical service, but if it did not want such a service it must offer co-operation somewhere. Accordingly he had projected this idea of a clinic which could take in the small factories in the district and pool the medical resources. What he wanted to see was a complete medical service which would avoid the rigidity of a legislative scheme and at the same time furnish all the benefits of co-operative effort. In a final remark about the London bus dispute Mr. Bevin mentioned that he was inclined to think that foot trouble might have an unlooked-for importance in the health of the drivers. The ball of the foot was constantly experiencing the vibration of the accelerator, and the foot might be used for dropping the clutch as often as 1,800 times in a seven-hour shift. He believed that this constant use of the foot affected the nervous system in a disadvantageous way. At any rate it was a matter for medical investigation. The posture in the driver's seat, causing a contraction of the stomach, might also account for not a few troubles.

SECTION OF HYGIENE AND PUBLIC HEALTH

Friday, July 23

Operative Treatment of Laryngeal Diphtheria

With Professor W. J. WILSON, President of the Section, in the chair, subsequently occupied by Dr. E. H. T. NASH, a discussion on the operative treatment of laryngeal diphtheria was opened by Dr. A. GARDNER ROBB (Belfast), whose paper was published in the *Journal* of August 7 (p. 264).

He was followed by Dr. J. M. KENNEDY (Sheffield), who discussed briefly the results which had been obtained in Lodge Moor Hospital, Sheffield, over a period of fifteen years. He gave comparative figures of total admissions, gross diphtheria mortality, and operative rate, and indicated the frequency of and the results following tracheotomy and intubation. A comparison of end-results seemed favourable to tracheotomy. Out of 10,372 patients admitted there were 327 deaths, a mortality of 3.15. Tracheotomy was performed on 352 cases and there were eighty-three deaths, a mortality of 23.57 per cent.

Dr. J. D. ROLLESTON outlined the history of operative treatment, and considered at some length the prognostic significance of serum reactions. His attitude towards serum administration was conservative; he had "never yet seen a case of diphtheria recover after intravenous serum which would not have recovered after intramuscular injections."

Dr. W. G. WILLOUGHBY (Eastbourne) presented the experience of a small community over a period of many years. He quoted figures from Vienna which showed good results following intubation alone. He reported also a case in which death immediately followed the injection of evipan in a case of diphtheria.

Professor J. JOHNSTONE JERVIS (Leeds) asked about the type of *C. diphtheriae* responsible for infection. Their

experience in Leeds was that no case of laryngeal diphtheria was caused by the "gravis" strain; in all such cases the "mitis" strain was found.

Dr. J. McI. GIBSON (Huddersfield) reported the continuance of gravis infection around Huddersfield, with very few cases of laryngeal involvement but two definite cases which were proved to be due to gravis strains. Dr. GARDNER ROBB closed the discussion, still maintaining the advantages of intubation.

Bragg-Paul Pulsator

Dr. C. J. MCSWEENEY (Dublin) read a short paper on the treatment of post-diphtheritic respiratory paralysis by the Bragg-Paul pulsator—an apparatus designed by Mr. R. W. Paul at the suggestion of Sir William Bragg. This apparatus was demonstrated by Dr. Kerridge at the Annual Meeting in Oxford last year. Among roughly 2,000 cases of diphtheria treated in the last two years thirty authentic instances of respiratory paralysis had occurred at Cork Street Hospital. Almost without exception the involvement of the respiratory muscles occurred during the sixth or seventh week. These cases had been treated with the pulsator, which consisted of a distensible rubber bag applied around the patient's chest and rhythmically filled with, and emptied of, air from a bellows. Twenty-two of the cases made uneventful recoveries. One of the eight fatalities had been treated in the apparatus for four days, when the machine broke down, and before a new part could be made the patient died. The remaining seven cases died of causes other than respiratory failure—six of them from late cardiovascular failure and one of them from gangrene a fortnight after coming out of the pulsator. There was no interference with the routine management, nursing, and treatment of patients, all of whom were nasally fed—since there was a coexistent pharyngeal paralysis—while being artificially respired. Questions from Dr. ROLLESTON and Dr. WILLOUGHBY were answered by Dr. McSweeney.

Diphtheria Immunization

Dr. G. A. W. NEILL (Huddersfield) read a paper on the variance in type distribution of *C. diphtheriae*. Professor JOHNSTONE JERVIS led the discussion which followed. Dr. E. H. T. NASH reported the end-results of an experiment in controlled diphtheria immunization, and stressed the value of publicity.

Dr. G. CHESNEY (Poole), in a paper on diphtheria immunization, pointed out that there was no such thing as inherited natural immunity to diphtheria. An active resistance of the body to the invasion of the bacillus was not present at birth. It must be acquired and could be acquired only by contact with the bacillus or its toxin. The discovery some fifteen years ago that diphtheria toxoid was as efficient as either the bacillus itself or its toxin in stimulating the production of the protective antitoxin placed artificial active immunization on a safe and secure basis. Dr. Chesney then discussed at length the factors which had to be considered in selecting an immunizing agent. To be regarded as eminently satisfactory a prophylactic should be (1) completely free from toxicity, (2) free from liability to cause sharp reaction, (3) capable of consistently producing a high grade of Schick immunity, (4) capable of rapidly developing this immunity with a minimum of injections, and (5) capable of producing an immunity sufficiently durable to protect from infancy to adolescence. Of the preparations most commonly used in this country toxoid antitoxin floccules, formol toxoid, and alum-precipitated toxoid approached most closely to the fulfilment of these conditions. There was little doubt that alum-precipitated toxoid was superior to both toxoid-antitoxin floccules and formol toxoid in meeting the need for the consistent and rapid production of a high grade and durable immunity, with a minimum of injections, but there was still some debate as to the requisite dosage and number of injections. Alum-precipitated toxoid used in two doses of 0.2 c.cm. and 0.4 c.cm. at an interval of four weeks gave a high level of Schick immunity. The initial small dose, acting as a detector of hypersensitive persons, eliminated reaction difficulties. The high Schick-negative rate obtained obviated the necessity for routine Schick testing after immunization. Of 1,468 children immunized in this way 1,300 were available for retest two months later. In only three children was the Schick test positive. The immunizing efficiency of the prophylactic therefore approached 100 per cent. Reactions immediately after injection caused no material trouble. The grade of immunity reached was high, for over 99 per cent. of the children tested with the "fourfold" Schick dilution were negative to this test. One hundred and twelve children who had been negative two months after immunization were retested eighteen months later; all were negative.

Dr. R. J. MAULE HORNE (Poole) said that he was an enthusiastic believer in diphtheria immunization, but that without great patience, persistent education, and especially great caution its success would be jeopardized.

Dr. J. GRAHAM FORBES described at some length the progress which has been made in the past five years in diphtheria prevention. At the same time he pointed out that diphtheria still exacted a heavy toll from the child population in England and Wales, with a yearly average for the past ten years of over 57,500 cases with 3,100 deaths, London alone having 11,000 cases and 400 deaths each year. He contrasted these statistics with those obtaining in New York and Montreal.

The meeting concluded with a paper from Dr. J. E. H. GATT (Malta) on the control of undulant fever in Malta with reference to the consumption of goats' milk. After discussing briefly the high incidence of undulant fever and the high infant mortality in Malta Dr. Gatt pointed out that since 1898 goats' milk had been banned as an article of food for all troops and marines in the Mediterranean, with the most beneficial results. Notification of the disease had been made compulsory, and the destruction of infected goats was carried out systematically. The civil Government had finally decided to exercise complete control over the milk industry of the island, and it was hoped to secure clean and safe milk for all at a reasonable price by proper pasteurization and distribution, and thus diminish the problems of undulant fever.

SECTION OF OTO-RHINO-LARYNGOLOGY

Friday, July 23

Care of Vocal Cords in Singers and Speakers

With Mr. HENRY HANNA, President, in the chair, the discussion on the care of the vocal cords in singers and speakers was opened by Sir MILSOM REES, whose paper was published in the *Journal* of July 31 (p. 208).

Mr. VICTOR F. LAMBERT (Manchester) said that this subject was the common responsibility of the laryngologist and the teacher of singing, but unfortunately there existed a lack of co-ordination between the two. Both parties were responsible, but a third, the student, was not free from blame. It was very difficult to persuade a school teacher or public speaker that it was not a "bottle of medicine" but rest and a course of voice production which he needed. Such a patient would consider his golf professional futile if he recommended a bottle of embrocation to correct a slice or a pull. At present the advice of the laryngologist was sought only in an acute crisis, whereas the speaker felt that mutual trust should be shown from the beginning of a student's career, when, if the whole of the vocal mechanism were examined, an anatomical record made, and abnormalities corrected before the method of production became fixed, surgery would do most good and least harm.

As the guest of Sir Milsom Rees at Covent Garden he had been able to see and appreciate the results of his treatment of the artistes there. He had been deeply impressed, and proposed in future to copy the technique. He had had personal experience of the tonic effect of the treatment. Of great importance were the earliest signs of failing voice: (1) the inability to start a tone softly without making use of a glottis stroke or jerk in the attack; (2) the inability to pass from a full voice to a half voice without discernible change in quality and adjustment of the organ itself. Constant hoarseness with paraesthesias and even actual pain added to the embarrassment of the singer. There might even be a feeling of tightness such as was experienced in globus hystericus. Bad habits such as hawking and hemming were adopted, and examination showed faulty apposition and bowing of the cords on phonation.

In the speaker's opinion "modulation" preceded "articulation," and he regarded singing not as an offspring of speech but as a descendant of a common physiological ancestor. It was, however, something of a trick, and one not easy to learn. Some were potentially better endowed than others, but none could become finished performers without practice and training. Practice produces habits, and the longer they continued the harder they were to change. Hence the importance of observation by a laryngologist, who would be able to recognize the bad effects of faulty habits while there was still a chance to eradicate them. The basis of treatment was: (1) vocal rest; (2) change in range if wrongly classified; (3) change in method of production (E. J. Moure). To this he would add the local treatment of Sir Milsom Rees. The greatest dangers to a singer's welfare were: (1) failure to recognize the individual requirements of each voice; (2) the tendency to emulate the voice of a distinguished artist although the voice might not be of the same pattern; (3) failure of a teacher to realize that bad methods would give results for a time and that a damaged mechanism would function a long while before failing; (4) the laryngologist who used "laryngitis" to cover the "multitude of his sins of ignorance."

Mr. C. J. BRENNAN could not agree with the apparent pessimism of Sir Milsom Rees with regard to the use of the human voice for singing. He thought that the human voice was admirably adapted to and was intended for musical use with words, called singing. The articulation of the consonants in singing remained the same, while the vowel sounds took on the notes of the melody. The speech must, however, be well placed for the vowel sounds to flow out, tonally expanded, to constitute natural singing. The difficulty with singers was that their "inner hearing" of their own voice gave but little idea of the outward product. He advised those present to listen to a record of their voice. A difficulty with young singers was the urge to do something. Hard work they seemed to feel would shorten the process. In fact, conscious effort interfered with the mechanism. "Let the voice sing, don't make it sing." It was no use looking for too early results. The control of breathing was vital. Add to this the advice to "sing as you speak, provided always that you speak properly." Range must be observed. Accidents were understandable if you realized the immense force passing the cords in a dramatic note. Perfect balance and control was essential, and he could imagine such balance being upset by a drop of moisture. In his opinion many could be good without necessarily being champions, and to be a champion needed some endowment and not brute force alone. One trouble for the student was the appalling division of opinion among teachers as to method.

Mr. DONALD WHEELER, a Vice-President, took the chair for the subsequent discussion.

Mr. T. B. JOBSON pleaded for a central authority from whom reliable voice-training teachers could be recommended. He felt that their appointment to schools should be more general. Mr. J. W. KILLEN (Londonderry) had come more to learn than to contribute. He had learned much. He stressed the importance of careful investigation of the posterior sinuses in cases of pharyngitis and laryngitis. Mr. L. GRAHAM BROWN said he only had occasional cases, but it was none the less important to treat them properly. He would like to know how much Sir Milsom Rees relied on the psychological effect of his treatment. He mentioned the functional aphonia after the first night and the visit with the anxious manager. He had done plenty of tonsil and nasal operations in singers, and felt that where he had not done good he had at least done no harm. Sinus diseases must be cleared up.

Mr. T. O. GRAHAM (Dublin) was interested in Sir Milsom Rees's explanation of the falsetto note. He could not understand how it could be produced by the false cords. He was anxious for advice on nodules; how long should the voice be rested? He saw teachers more than singers, and he removed the nodes when they were fibrosed. In a case of recurring submucous haemorrhage he had used the galvanocautery. He felt that the less medication and the less that was done generally the better the results. Mr. C. DE W. GIBB (Gloucester) found it very difficult to get breath control taught. Mr. E. S. B. HAMILTON (Manchester) asked for information as to diet and exercise, and especially with regard to alcohol. He had once used an injection of strychnine. Mr. R. R. WOODS (Dublin) asked if Sir Milsom Rees had used the stroboscope, and wanted a definition of "catarrh" as used by him. Dr. H. HANNA (Belfast) stressed the importance of co-operation between teacher, student, and laryngologist. It was always difficult to get the subject to rest. Mr. T. A. CLARKE (Canterbury), Mr. F. C. W. CAPPS, and Mr. F. A. MACLAUGHLIN (Belfast) also spoke.

Mr. LAMBERT in reply disclosed that he had started life as a singer. He had been impressed by the real physical effect of Sir Milsom Rees's spray treatment. There was far more than psychological effect in it. In his view the control of breathing must be from below; the larynx had as much to do with muscle tension and balance as it could manage without acting as a sphincter. Captain BRENNAN agreed that breathing was important. He quoted the instance of a Parisian vogue for "abdominal" breathing in singing. He felt that control of the "forward" end of breath flow was as important as the lower end.

Sir MILSOM REES said it had been his "job to crab singers." Managers asked for his advice about contracts. Madame Schumann owed her long career to short, narrow, and elastic vocal cords. One could tell from the examination of a larynx something about the "life" of a voice. Better tuition had given a greater number of good voices, but there were now fewer "excellent" voices. The treatment of nodules depended on "when they came to you." A vesicle required three or four days' rest, with an astringent spray and Moure's exercises, a superficial haemorrhage seven to ten days' rest. Since the war he had not seen one singer's nodules which needed removal. If they recurred it was due to bad production. Occupational nodules (hawkers', etc.) should be removed. Treatment did help other than psychologically in that a free nose and a clear head gave freedom of production. Alcohol was fatal: first, it was not necessary, and, secondly, it might lead to intoxication. Strychnine he had never tried.

Volume XV of the *Guide to Current Official Statistics* has been prepared and issued by the Permanent Consultative Committee on Official Statistics. It is a systematic survey of the statistics appearing in all official publications issued in 1936, and the nature of the information available on any subject and the official publication in which it is contained can be readily ascertained. The *Guide* contains over 400 pages, and is obtainable from the sale offices of H.M. Stationery Office or through any bookseller, price 1s. (by post 1s. 6d.).

Nova et Vetera

A BIBLIOGRAPHICAL BIBLIOPHILE

Of medical men who have sought and found recreation or a career in literature there is no end. Literary men who have interested themselves in the history of medicine, while not so numerous, have often become its greatest ornament. How commendable, therefore, is the policy of the Royal Society of Medicine's History Section to recognize other than medical qualifications for its membership.

Leonard Leopold Mackall, president of the Bibliographical Society of America, who died on May 19 at the age of 58, was fond of describing himself not as a medical historian or librarian, but as a mere bibliophile—bibliographer or bibliographical bibliophile. A familiar figure in Osler's world, a glance through the *Bibliotheca Osleriana* (the completion of which had been entrusted to him among others) shows his name as donor of some of its most precious items, accompanied by meticulous bibliographical notes. He helped to see Osler's *Evolution of Modern Medicine* through the press, and for the *Contributions to Medical and Biological Research* dedicated to Osler he wrote a scholarly paper entitled "Servetus Notes." He was interested in the early history of appendicitis. The New York Academy of Medicine in 1930 had the happy idea to make him its consultant in bibliography, thus publicly recognizing his services to medicine.

As a bibliographer Mackall delighted in accuracy and the over-elaboration of what to some are dry and soulless minutiae, but his literary style was pleasant and his humour refreshing.

Oslerians on both sides of the Atlantic will miss his help, always generously given, with their bibliographic and historical research; will miss, too, his handwriting, so large, so sprawling, and yet so characteristic and so friendly.

W. R. B.

AN AMERICAN FIELD DRESSING STATION SEVENTY-FIVE YEARS AGO

The following account of a Field Dressing Station, Northern, during the American Civil War (1861–2) is a copy of the description by the late Lieut.-General E. O. Hewett, C.M.G., written when he was military observer for the British Government. At that time he was a captain in the Royal Engineers. Lieut.-Colonel E. Hewett, O.B.E., C.M.G., D.S.O., has kindly given me permission to publish this extract.

"I was travelling with a Doctor (British) whose chief interest of course is the hospitals. I always think it as well to see everything, so, having half a day to spare, I agreed to go with him over the main field hospital camp at Smokestown. I am glad now that I did so, but I'd never care to attempt the same a second time. There were some 3,000 wretched creatures (not sick but all brought for operations, lying under the trees within a space of say 300 yards square. Most had straw to lie on, but not all, and there were a few tents. There were about 60 surgeons without coats (chiefly French, German, and Irish) covered with blood and dirt, chatting, arguing, laughing and swearing, and cutting and sawing more like devils and machines than human beings. Large heaps of legs and arms were piled here and there, all sizes and stages of decomposition; the odour was fearful, and the whole air felt thick and putrid, while myriads of flies buzzed and darted rapidly about. I saw about fifty limbs taken off during the two hours I remained there.

"The Yankees have creatures they call Medical Cadets, and these fiends, the moment a limb was off would pounce on it from behind trees and fight for it, and in a few minutes it would be cut into little bits for practice.

"I thought I could stand a good deal, but the stench, heat and flies was so fearful that it made me feel rather queer, and when I saw one of these cadets seize a leg almost before it was off, and holding it by the toe, run away with it, still quivering and bleeding, and ragging and bumping it along the ground, while the other devils chased him, it made me feel for a little time so sick that I felt myself grow pale, and dared not speak for a few minutes. However, I was determined to conquer it and did, though I could hardly help hitting some of the surgeons and cadets. I could talk and help the poor fellows themselves.

"War certainly has two sides to it, though happily it is seldom or never that such repulsive scenes as this take place. It was doubly sad, too, as all the men spoke our language, and looked like Englishmen. The Yankees are a queer people; they have no delicacy in taste or feeling. We always keep the actual operations (when and where practicable, as in this instance) a little apart from the sight of the sufferers or hidden a little, but the Yankees do not attempt his—one thing is that most of their surgeons are Irish and German adventurers who know nothing, and care little, for the Americans themselves—but still to me do not appear to care, whereas it would not do with our men.

"The Yankees are bearing the pain marvellously, and are most patient and cheerful, poor fellows; it was grievous to see such splendid men wrecks for life, and sometimes you would see an old man or a young boy amongst the equally shattered but equally calm."

Bournemouth. JAMES EWING.

ANNALS OF MEDICAL HISTORY

The May number of the *Annals of Medical History*[1] opens with Dr. R. N. de Jong's account of chronic hereditary chorea, usually called Huntington's chorea. Although giving George Huntington, who died in 1916, credit for the best account in 1872, Dr. de Jong points out that the features of this chronic chorea had been described before by C. O. Waters (1841), C. R. Gorman (1848), Germain Sée (1850), and I. W. Lyon (1863). Huntington's description was based on cases he had seen with his father and grandfather on Long Island, and so is a result of inherited observation. In the article entitled "The Strange History of the Vesicle in Scabies" Dr. Montgomery recalls the time, more than a century ago, when scabies was one of the most important diseases in the philosophy of medicine, and was claimed by each of the opposing forces of the humoralists and the contagionists. Dr. Jameson of Saranac Lake pays a tribute in "John Leake and Childbed Fever" to a London obstetrician in the eighteenth century who was overshadowed by the assertive personality of John Denman, "who lost no opportunity, by fair means or foul, to disparage a rival's ability." The plague of 1603 in England is described by Mr. Charles Mullett. Under the title of "Moon Madness" Dr. W. H. Stahl discusses the superstitions about the influence of the moon on menstruation, childbirth, epilepsy, and mental disorder; and in Chapter V of his essay "The Doctor on the Stage," Dr. H. Silvette, writing on the *virtuoso*, has much to say about Samuel Pepys and the Royal Society.

FAR EASTERN RURAL HYGIENE

CONFERENCE IN JAVA

A Conference on Rural Hygiene for Far-Eastern Health Administrations, summoned by the League of Nations Health Organization, opened at Bandoeng in Java on August 3. It is one of a series that have been, or will be, held in different parts of the world. The proposal to hold this conference was made at the Assembly in 1932 by the representative of India, supported by the representative of China, and was repeated with further support at the Assembly in 1934. The Bureau of the Health Committee was asked as early as 1932 to make a preliminary study of the question and obtain the opinion of the advisory council of the Eastern Bureau of the Health Organization in Singapore, and that council reported in favour of holding the conference. This reflects the growing interest taken in raising the standards of living of the rural population, which comprises the overwhelming majority of the teeming millions of the Far East.

A preparatory committee made a tour around India, Burma, Siam, Malaya, Indo-China, the Philippines, the Netherlands East Indies, and Ceylon, and drew up a report for discussion at the conference. The purpose of this was to state on the basis of a mass of facts, observations, and experiences the fundamental terms to which the problem of rural medicine and health can be reduced in the conditions prevailing in the Far East. The chapters of the report give a general indication of the matters discussed under each item of the agenda of the conference. The agenda comprised: (1) health and medical services; (2) rural reconstruction and collaboration of the population; (3) sanitation and sanitary engineering; (4) nutrition; (5) measures for combating certain diseases in rural districts.

Health and Medical Services

The first chapter surveys the different forms of health and medical services that exist in the Far Eastern territories represented at the conference. It draws attention to "the burning question whether, having regard to the desires of Asiatic society, one or more than one type of doctor should be trained. In other words, should there be only one body of fully trained medical men, or should there also be schools for the rapid and hence incomplete training of students?" The pros and cons of the practice of training so-called "semi-qualified" or assistant doctors are discussed, and the possible alternative of auxiliary medical staff under efficient supervision by doctors trained on European lines is indicated.

"European medical science is everywhere invading Asia, where it encounters what has remained of the old medical lore of Hindu medicine, the Arabian school, and the old Chinese institutions, all of them based upon traditional empiricism. The importance of all this should not be underestimated, and official medical science, over-confident of its own infallibility and of the inferiority of this ancient popular medicine, has made the mistake of scorning it. Yet many an old precept can be found which accords with our own views, even though put in a somewhat different form. Thus, frequently we strongly oppose the use of the medicinal herbs and other substances of popular Eastern medicines, forgetting that our own pharmaceutical industry has produced, in addition to sound and valuable medicines, much that it would have been better never to administer to any sufferer. The study of these ancient medical cultures and of their remaining vestiges would be of value. They should have a place in the training, so that the young doctor may have at least an elementary knowledge of these questions when he begins practising. Such knowledge is essential if he is to adapt himself to his social environment. Lastly, it would be desirable honestly to consider how far these old medical traditions can be reconciled with our own principles, instead of rejecting them in a body as useless and obsolete."

Rural Reconstruction and Sanitation

The second chapter begins by pointing out that there is no more familiar cry in the newspapers of every Far Eastern country than rural reconstruction. It is also a cardinal point in the policy of Governments and in the activities of voluntary bodies and charitable associations of all kinds. This is particularly the case in India.

"It is perhaps somewhat strange that this concentration of interest in the rural problem should occur simultaneously in all these countries, and that it should be so recent and so comparatively sudden. But it is indisputable that a reorientation of governmental policies is taking place, and that the needs of the distant and inarticulate peasant are being weighed in the council chambers where hitherto his voice has been little heard. . . . With the perception of the possibility of improved conditions of life is growing the desire to attain them. The progress of education is having its effect. Interest is being shown in the improvement of health, in economic problems, and in all matters which affect the maintenance of a reasonable standard of living. The dullness of village life is being dissipated by the dawn of rural reconstruction."

In this connexion the importance of education and of the spread of the co-operative movement is stressed, and methods by which health authorities enlist the interest and support of the peasants are described.

Chapter 3 of the report covers the subject of sanitation and sanitary engineering in the agenda. Housing, drinking-water supply, latrines, manure and household refuse, and fly control are all discussed.

Food Problems

The fourth item on the agenda is covered by the chapter on nutrition in the preparatory report. Investigations into the state of health of the peoples of the East, no matter what their starting-point, lead back invariably to the question of nutrition. Dietetics is a branch of science which has a variety of aspects in Asia; there, even more than elsewhere, dietetic research requires the close co-operation of chemists, physicists, agronomists, physicians, veterinary surgeons, and economists.

The prevailing opinion is that the state of nutrition of the populations of rural districts is not wholly satisfactory in any of the Asiatic countries. It is thought that of the 1,150,000,000 inhabitants of that continent not less than 75 per cent. have a diet below the standards fixed by European science. From various publications, and from the information that the committee collected during its tour, it appears that a large part of the population is living on the border-line of the minimum requirements, while millions are even below that level.

"These statements should, however, be accepted with some caution, because an examination of the studies so far made in Asia shows that few accurate statistics are available. Whereas in other continents there has been on occasion overproduction of food at different times and places, so that production has been restricted and food even destroyed, this has never occurred in Asia. Everything produced is always quickly consumed, and, so far from there being a limitation of crops, the dominant question everywhere is how to increase them. An exception may be made as regards a few articles intended for the world market, such as sugar and copra. The food problem in the East is almost exclusively a rural problem, since more than 90 per cent. of the population live outside the towns."

This chapter reviews such subjects as the composition of the diet of the rural populations, the chemical composition and biological value of the different foodstuffs, different diseases of alimentary origin, and the proportion of the family budget spent on food. The final remarks are to the effect that a well-fed and healthy population is vital to every country for its development and future. But in all Asiatic countries only relatively trifling sums are allocated to the detailed study of national nutrition or to attempts to improve it. Some authorities think this is a field that should rather be left to private initiative. The public authorities still fail to appreciate the great importance of food problems. Only in the event of war or economic depression do they decide to act. The growth of the population and the ensuing increased importance of ade-

quate nutrition will help to wean most Governments from this short-sighted policy. The assertion often made that very primitive peoples show an unfailing intuition in regard to their food supply in time of need is obviously exaggerated, and, indeed, is contradicted by practical experience. A small measure of intuition there certainly is, but it can easily be overrated. If the conference helps to bring about a change in the views of some of the Governments that will in itself be an appreciable advance.

Need for Administrative Contacts

The final chapter reviews the chief diseases affecting the rural population of Far Eastern countries and the measures for combating them. These diseases are: malaria, plague, ankylostomiasis, tuberculosis, pneumonia, yaws—described as "the rural disease *par excellence*"—and leprosy. One of the chief results expected from the conference is improved contacts between the health administrations of different countries and colonies, and even of different provinces in, for instance, India. At present health administrations often work at similar or identical problems without knowledge of each other's activities and their results.

THE NATION'S HEALTH SERVICES

ANNUAL REPORT OF THE MINISTRY

The eighteenth annual report of the Ministry of Health,[1] for 1936–7, was published last week. The seven parts into which it is divided deal successively with the Ministry and the public, finance, public health and assistance, housing and town planning, local government organization and finance, national health insurance and pensions, and the work of the Welsh Board of Health. In presenting the report Sir Kingsley Wood refers to the striking progress in national health since the Ministry of Health was first established in 1919, the post-war housing achievement and accompanying changes for the better in living conditions and social habits, the various local health services, and the health insurance and contributory pensions schemes. Turning to the period covered by the present report, he suggests that this and the current year may appear to the future historian as noteworthy for the steps taken to strengthen what seemed to be the weakest links in the existing chain of public provision for health and welfare.

"Thus the setting up on a national scale of a public service of skilled midwives, with the detailed improvement of their existing maternity services by a large number of local authorities, was designed to strengthen these services at their most vulnerable point—the mother's own life and health. Again, the measures in hand to extend the child welfare and school medical services upwards and downwards respectively, by providing better attention for children too young to attend school and so improve their health still further, are intended to close this gap in the existing facilities. At the time of writing proposals are before Parliament for closing another gap—that between the school medical service and entry into the health insurance scheme at the age of 16. Finally, mention should be made of the Act of Parliament, passed while this report was in the press, extending the existing contributory pensions scheme so as to allow independent workers and professional and other persons of small means to insure for pensions if they wish to do so."

£65,000,000 of Exchequer money was spent in 1936 on services administered by the Ministry, £2,200,000 of which went on central administration. The remainder consisted of grants to local authorities (including "block grants" of £40,000,000 and housing grants of £14,000,000) and to national health insurance funds. The Ministry also accounts for the national health insurance funds and administers the Contributory Pensions Scheme, involving the expenditure of £75,000,000.

Maternity and Child Welfare

There are now over 3,000 infant welfare centres (fifty-eight more than in 1935) and 1,568 ante-natal clinics (seventy-seven more than in 1935). The maternal mortality rate was 3.81 per 1,000 live births—the lowest rate since 1922. The new Midwives Act will ensure a qualified midwife for every confinement, whatever the patient's means. The infantile mortality rate was 59 per 1,000 births—the third successive year in which it has been below 60—and would have touched a low record but for bad weather, which increased the deaths in the first quarter of the year. Forty-six authorities have established separate "toddlers clinics" at their centres, and fifty-six have made the school medical service available for the younger children. Out of 374 maternity and child welfare authorities 364 supply free or cheap milk to expectant mothers, 363 to nursing mothers, and 362 to young children.

Infectious Diseases

Tuberculosis mortality was the lowest on record. For example, in 1931 there were 29,658 deaths from pulmonary tuberculosis and 6,160 from non-pulmonary tuberculosis; the figures for 1936 are 23,801 and 4,467 respectively. There were 121,951 *x*-ray examinations in connexion with the tuberculosis dispensary service in 1936, compared with 63,823 five years previously.

There were 3,232,986 attendances at venereal disease centres during 1936, compared with 1,534,000 in 1921; but over two-fifths of the new cases dealt with in 1936 proved not to have venereal diseases. The total number of cases of syphilis dealt with at English treatment centres has been reduced by 56 per cent. since 1920.

Notifications of diphtheria were 7,290 less than for 1935, but still considerably in excess of those for 1933. Encephalitis lethargica continues to decline, notifications being less by 38 per cent. than in 1933. There were 2,493 notifications of enteric fever (including paratyphoid), compared with 1,750 in 1935. The increase was mainly the result of an outbreak of 718 cases at Bournemouth, Poole, and Christchurch last summer, with fifty-one deaths and was due to the drinking of infected raw (that is, unpasteurized) milk. An outbreak of over 160 cases of scarlet fever at Doncaster and one of gastro-enteritis at Wilton were also traced to the drinking of infected raw milk. As is stated in the introduction to the section on public health, these "distressing outbreaks of milk-borne disease . . . have emphasized the importance of public safeguards for the milk supply and the protection afforded by proper pasteurization."

Milk and Nutrition

The report stresses that national health cannot be reached or maintained without food adequate both in quantity and in quality. Special interest therefore attaches to the first report of the Advisory Committee on Nutrition, which drew attention to the great improvement in the health of the people as a result of the practical application of the discoveries in the science of nutrition. There is, nevertheless, "a large number of disturbances of nutrition, amounting in some cases to actual disease, which are due to improper or defective diet." The Advisory Committee has pointed out that there is, accordingly, much room for further improvement in the health and physique of the nation, which can be promoted by the consumption of adequate amounts of the "protective foods," the most important being milk and its products, green vegetables, fruit, and eggs. The consumption of a sufficient quantity of milk is regarded as the "key to proper nutrition." But the consumption of liquid milk per head has slightly declined since before the war. The

Advisory Committee recommended that the daily consumption of milk should be about two pints for expectant and nursing mothers, from one to two pints for children, and not less than half a pint for the rest of the population—equivalent to about seven-eighths of a pint a day per head of the whole population. At present the consumption of milk in all forms is about half a pint a day per head, or only 60 per cent. of the recommended amount.

Since the coming into operation of the Milk (Special Designations) Order, 1936, the only grades of special milk now officially recognized are "tuberculin tested" and "accredited." Both these, like ungraded milk, may be sold as "pasteurized," but if so the pasteurization must be effected in a specified manner—that is, the milk must be retained at a temperature of 145° to 150° F. for at least thirty minutes, and a sample taken at any time after pasteurization and before delivery to the consumer must not contain more than 100,000 bacteria per millilitre.

Public analysts analysed 146,438 samples of food and drugs, of which 7,802 (5.3 per cent.) were reported against: 80,082 of the total were samples of milk and 7,588 were samples of butter.

Sanitary and Other Services

The three services of water supply, sewerage and sewage disposal, and public cleansing (excluding street cleansing) now cost local authorities £22,400,000 a year in maintenance costs alone; in 1900 the corresponding figure was only £5,000,000. Public cleansing, the oldest sanitary service of all costs the rates about £11,000,000 a year. House refuse alone amounts to about one ton per year (or 6 lb. a day) per house. During the past five years the average weight of refuse has come down by 15 to 20 per cent., the result, it is thought, of less cinder and fine mineral dust, due to the greater use of improved fireplaces and of gas and electricity.

The Ministry sanctioned loans totalling £3,196,002, compared with £2,467,245 in 1935, for parks, recreation grounds, and playing fields. This includes the purchase of 9,059 acres (including 1,030 acres specifically for games), compared with 4,732 acres in 1935. Large schemes were approved for covered baths at Coventry, Crewe, Kingston, Lancaster, Northampton, and Sutton and Cheam, and for open-air baths at Brighton, Nottingham, Stroud, and West Ham. The cost of a number of open-air pools in the special areas will be assisted by special Government grants: these include schemes at Abercarn, Bridgend, Caerphilly, Merthyr Tydfil, and Mountain Ash.

Hospitals

Local authorities are steadily building up a service of general hospitals as an integral part of municipal health services, and in association with the voluntary hospital system ninety-two Poor Law institutions, containing 50,073 beds, have now been appropriated in whole or in part as public health general hospitals: "The test for admission is no longer destitution, but the need for the kind of treatment which the hospital is able to give." The report points out that an important result of appropriation is to facilitate co-operation between the county or county borough council and the voluntary hospitals in the area, by way of engaging members of the staffs of voluntary hospitals, and by arranging what kinds of illness should be treated in the two classes of hospitals and for transfer of patients from one to the other. It has been estimated that local authorities provide about seven-tenths of the total number of hospital beds in England and Wales, or, if accommodation for infectious diseases is excluded, about two-thirds.

"The power conferred on county councils to provide general hospital accommodation, the concentration of the responsibility for public provision of the various forms of accommodation for the sick in the hands of a single authority in each area, and the subsequent activity in hospital provision, have thrown into relief the urgent necessity of securing in every area that the relation between the public and the voluntary systems should be co-operative and complementary and not overlapping and competitive. This task is at once most pressing, and presents most complications, in the field served by the general hospital for the acute sick.

"Section 13 of the Local Government Act of 1929 laid down a minimum requirement—that is, that a local authority when making provision for hospital accommodation in discharge of the functions transferred to them by the Act should consult such committee or other body as they considered represented the voluntary hospitals serving the area. In the early surveys, while it was clear that some local authorities realized the importance of co-operation with the voluntary hospitals, indications were met with that consultations were being regarded in a few areas as being merely a matter of form, while other authorities were satisfied with the minimum required by the Act. The Minister has taken every opportunity of urging the necessity of close and continuous co-operation, and he is glad to know that during recent years much has been done to secure this."

Housing

The year under review was the fourth of the "five-year plan." Up to the end of 1936 100,355 houses had been demolished and 127,553 houses built to replace them. The end of the five years is expected to see the completion of the programmes, except in London, Birmingham, Liverpool, Manchester, and Leeds, which have special problems necessitating a further period of time. The nation-wide survey of overcrowding revealed 341,554 of the 8,924,523 dwellings inspected to be overcrowded according to the standard of the Housing Acts. Fresh overcrowding ceased to be permitted for the areas of 96.6 per cent. of the local authorities during the year.

Local Government Finance

The three main sources of local government revenues are rates, Government grants, and receipts from trading services, house rents, and miscellaneous income. In 1934–5 £154,782,080 was collected in rates; £124,353,931 was received in Government grants (of which £45,409,836 was block grant and £40,407,467 for education); and £181,568,094 was derived from other sources of income, including £116,000,000 from trading services (chiefly water, gas, electricity, and transport). The total expenditure of local authorities for the same year was £80,657,889 on capital account, £100,984,164 on loan charges, and £353,775,105 on revenue account other than loan charges. The heaviest single item of expenditure was education. The gross outstanding loan debt of all local authorities at March 31, 1935, was approximately £1,421,500,000, a third of which was for housing.

National Health Insurance

In England and Wales 16,500,000 men and women are covered by the statutory benefits (cash and medical attendance) of national health insurance, and over two-thirds of them are also entitled to additional benefits, such as dental and ophthalmic treatment. As a result of better trade conditions the number of persons insured for national health insurance increased by 2.8 per cent. during the year, and the amount of contributions by 4.8 per cent. The revenue of 1936 exceeded that of 1932 by £3,000,000—representing 80,000,000 working weeks. Medical benefit cost £9,430,000, of which £6,868,900 went to doctors for attendance and treatment and £2,084,600 to chemists for drugs and appliances. As regards additional benefits, £2,174,000 was allocated to dental and £542,663 to ophthalmic benefit.

The report contains, as is customary, a separate section on the work of the Welsh Board of Health, and concludes with fifty-six appendices and a full subject index.

Local News

SCOTLAND

Research in Animal Diseases

At the annual meeting of the Animal Diseases Research Association at the Moredun Institute, Edinburgh, on July 28, the disease of horses known as grass sickness was discussed. An extensive field experiment financed by the Government had been conducted to determine whether a toxin found in cases of the disease was a causal factor, and it was reported that this toxin did not appear to be of primary significance. This negative result at all events cleared the way for future work. Dr. Russell Greig said that this field experiment had been the most extensive and most closely supervised of its kind which had ever been attempted in this country. The toxin had been administered to about forty horses and did not produce grass sickness. About 1,000 horses had been treated by a vaccine prepared from the toxin, with 2,000 unvaccinated horses as controls, and the evidence obtained from this was also of a negative character. With regard to bovine abortion, Dr. Greig said that systematic research had shown that a vaccine was capable of affording a certain amount of protection to small animals, and this work was now being applied to bovine animals. The disease of louping-ill in sheep had been treated with good results by a vaccine, of which 107,000 doses had been issued by the institute last year, and lamb dysentery serum, of which 71,300 doses had been issued, had also proved satisfactory.

Incapacitating Sickness in Scotland

The sixth report upon incapacitating sickness in the insured population of Scotland, dealing with the period from July 1, 1935, to June 30, 1936, shows that chronic incapacity is on the increase. The most variable cause of incapacity from year to year had been influenza, but during 1935–6 the lowest number of cases since recording began had been attributable to this cause, and a fall of 5 per cent. in the incidence of incapacity compared with that of the previous year was more than accounted for by the low influenza prevalence. Notwithstanding this drop, the number of days of incapacity per insured person had risen by 5 per cent., or fully half a day per person per annum over those of the previous year. The volume of incapacity per person per annum amounted to eleven and a half days, which formed a new high record. The duration of incapacity had also increased in all conditions except those of the respiratory diseases, general diseases, diseases of the circulatory system, and pregnancy. The increase in chronic incapacity affected particularly the average duration of illness—fifty-two days—which exceeded anything previously recorded. The insured population for the year had been 1,725,198, composed of 1,134,681 males and 590,517 females. This was an increase on the number of 1,708,494 for 1934–5. The days of incapacity for the year amounted to 12,394,412 for males, and 7,350,572 for females. The total days lost were therefore approximately 20,000,000—the equivalent of 54,000 persons constantly sick throughout the entire year. There was a loss of 1,166,406 more days than in 1934–5, or as compared with the average of the previous five years an increase of 2¼ million days.

A percentage analysis of the causes of incapacitating sickness showed diseases of the respiratory system to be responsible for 33 per cent. of the cases, rheumatic diseases coming next with 12 per cent., diseases of the digestive system 11 per cent., skin and septic conditions 10 per cent., and various forms of violence 10 per cent. The days of incapacity per person showed considerable geographical variation, being, for example, between eight and nine days in Edinburgh, ten to eleven days in Glasgow, eleven to twelve days in Dundee, and twelve to thirteen days in Aberdeen. The occupational incidence of sickness also showed great variation; those males engaged in mining and quarrying showed an outstandingly high rate, 70 per cent. in excess of that for all males. Textile and paper workers also had a rate of incapacity 7 per cent. above the average. On the other hand, persons engaged in personal service—for example, domestic servants and chauffeurs—showed a rate 30 per cent. below the average, and clerks, shop assistants, etc., had an incidence of incapacity 20 per cent. below the average. Among females women engaged in transport work showed 30 per cent. above the average, while among those engaged in metal trades and in making foods and drinks the rate was 30 per cent. below the rate for all women. The report directs special attention to the subject of chronic incapacity, and states that chronic illness accounted during the year for more than half of the total volume of incapacity in the insured population of Scotland, or 11 million out of 19¾ million days. It has been argued that there might be a progressive building up of excess of permanent invalidity, and that only in 1961, when the Insurance Act will have lasted for a period equivalent to the span of insurance life—that is, sixteen to sixty-five years—will stability be reached. It is pointed out, however, that the proportion of chronic cases surviving to-day whose incapacity began in the early years of the Act is inconsiderable. The report may be obtained from H.M. Stationery Office, 120, George Street, Edinburgh, price 9d. net.

ENGLAND AND WALES

Welsh Board of Health Report

The report of the Welsh Board of Health for 1936–7, which has now been published as part of the Annual Report of the Ministry of Health (H.M. Stationery Office, Cardiff, price 5s. net) reveals steady progress in the public health services of the country. The infant mortality rate of 62 per 1,000 births and the tuberculosis death rate of 861 per million of the population are in each case the lowest yet recorded for the principality. The maternal death rate has also declined, and the rate of 5.17 per 1,000 births for 1936 is, except for 1931, the lowest recorded since 1926. It compares with 6.08 for the period 1933–5. On the health insurance side sickness experience appeared to be on the down grade generally, but an epidemic of influenza in December and January caused increased expenditure, which resulted in the total sickness expenditure being heavier than in 1935. Owing to improving industrial conditions many persons previously unemployed are qualifying afresh for sickness and disablement benefits, and thus become entitled to all the benefits provided under the National Health Insurance Act. During the year the Midwives Act, 1936, came into operation, and proposals under the Act for the provision of a domiciliary service of salaried midwives have been submitted by all the local supervising authorities. The treatment of tuberculosis is carried out in Wales by the Welsh National Memorial Association on behalf of the county and county borough councils, and a new scheme has been made by the Minister of Health providing for the payments by the councils for the third fixed grant period (1937–42). According to the report facilities for the treatment of the sick are provided by local authorities at forty-three institutions (5,168 beds) maintained under the Poor Law Act, 1930, and at five institutions (438 beds) maintained under the Public Health Acts. As regards Poor Law domiciliary medical relief, it is mentioned that the "panel" system is no win operation in the greater part of Glamorgan and that one other county council has made similar arrangements in three of its medical relief districts. Approximately 979,000 persons (763,000 men and 216,000 women) in Wales are insured for national health insurance purposes out of a

total population of 2¼ millions. The total receipts (inclusive of Exchequer grants) during 1936 were £1,983,000, and £1,662,000 was spent on benefits and £324,000 on administration. Sickness benefit accounted for £575,000, disablement benefit £363,000, and medical benefit £545,000. The number of doctors participating in insurance practice was 969.

The Red Cross Rheumatism Clinic

The annual report of the British Red Cross Society's clinic for rheumatism records continued progress, the attendances in the general department during 1936 numbering 95,622, an increase of nearly 6,000 on the previous year. Although the number of advanced cases of rheumatism is still comparatively large, it is stated that a greater proportion of patients in the early stages of the disease are now seeking treatment. With regard to the results of treatment 60.3 per cent. of cases are classified as free from subjective symptoms and 29 per cent. as definitely improved; the first category shows a slight preponderance of men, the second of women. The report stresses the importance of protracted convalescence in healthy surroundings for early cases of rheumatoid arthritis, and suggests the desirability of a building for this purpose being made available within a reasonable distance of London. Facilities for research on a large scale are also urgently required, whereby the valuable clinical material passing through the clinic may be utilized for the furtherance of knowledge of rheumatic diseases. Under present conditions the ever-increasing number of routine examinations and treatments demand not only the whole time of the staff but also all available accommodation at the clinic. The question of in-patient treatment is also a pressing one. A number of beds are reserved for rheumatic patients by the London County Council at St. Stephen's Hospital, but the report emphasizes the importance of the provision of in-patient accommodation under the direct supervision of the staff of the clinic. It is obvious that the time is now ripe for expansion, and that the work of this institution will be seriously handicapped until these deficiencies can be made good. The financial report shows an increasing deficit, the adverse balance standing at more than £4,200 at the end of the year. It is to be hoped that means may be found to enable the clinic, which in a few years has made for itself a great and deserved reputation, to be placed on a more satisfactory financial footing, and to secure the provision of the three things so essential for its future progress—namely, research facilities, in-patient accommodation, and a convalescent hospital.

Heatherwood Hospital, Ascot

The extension of this hospital, which the London County Council in 1935 decided to provide at an estimated cost of about £72,000, has been completed and is now in occupation. Heatherwood Hospital was originally established in 1920 by the council of management of the United Services Fund for children of ex-service men suffering from surgical tuberculosis and other orthopaedic diseases. In December, 1929, the Fund offered to transfer the hospital to the L.C.C. as a free gift after the cessation of the Fund in about eight years from then, and this generous offer was accepted. Subsequently the Council agreed to take over the hospital on October 1, 1934. The decision to enlarge Heatherwood Hospital was taken in connexion with a proposal to change the user of Princess Mary's Hospital for Children, Margate. The 271 beds at the latter hospital had been used for surgical tuberculosis, but there had been a progressive diminution in the number of such cases and parents were often unwilling to send children who were seriously ill, and likely to be away from home for prolonged periods, to a hospital so far from London. From many points of view it is desirable that children with surgical tuberculosis should be nearer to London, an important consideration being the readier availability of the Council's consultant and specialist organization. It was decided, therefore, to convert Princess Mary's Hospital into a much-needed seaside convalescent hospital for London women and to extend Heatherwood Hospital by providing an additional 100 beds. This hospital is fully equipped for the types of case sent there, and being situated, within reasonable distance from London, in 55 acres of grounds partly wooded and partly laid out as gardens, is very suitable for the purpose. The hospital, as the L.C.C. took it over, consisted of three single-story ward blocks, one for children up to the age of 7 and one each for girls and boys over that age, with an up-to-date light treatment block, workshops for the making of splints and surgical appliances, a hospital school, administrative buildings, and staff quarters. The design of the new block was decided on after careful consideration of other modern hospital accommodation in this country for the type of case sent to Heatherwood. It is a one-story double ward block for 100 patients planned for effective open-air treatment.

Correspondence

Treatment of Giant-cell Tumours of Bone

SIR,—It was with surprise that I read the dogmatic statements of some surgeons at the recent Belfast meeting that the treatment of giant-cell tumours of bone should almost always be operative (*Journal*, August 7, p. 285). I had the good fortune to attend an animated discussion on this subject at the Presbyterian Hospital, New York, just over a year ago. Since American figures were quoted freely at Belfast it may be of interest to record the views of some leading New York surgeons.

Excitement over the subject was aroused by a medico-legal case. A man had been knocked down, and a radiograph taken soon afterwards showed a giant-cell tumour in the femur above the knee-joint. This was treated with *x*-rays, which was then, as now, considered the treatment of choice. No biopsy was made at first. About two months later another radiograph was taken in order to note the progress, and the lesion appeared larger. Some said this meant it was malignant, but others, notably Dr. Haagensen, said that this was the normal appearance of a giant-cell tumour at this stage of treatment, which should continue. It was decided to operate, however, and a frozen section was made; this was not conclusive, and the limb was amputated. Later sections showed that the tumour was benign. The man claimed damages from the person who knocked him down on the grounds that the tumour did not respond to *x*-ray therapy because of the accident. The jury failed to agree on four occasions, and I do not know the outcome of the case. Professors Ewing and Wood were called in on this case, and said that they were sure the case would have progressed well had *x*-ray therapy only been used.

At the discussion it was said that the radiological diagnosis of giant-cell tumour in bone was correct in about 95 per cent. of cases, and for these there seemed no doubt that *x*-ray therapy was the treatment of choice. There can be no question that it does give a complete cure, and the difference in the patient's comfort with this treatment as compared with that of surgery is so obvious that it needs no comment. The first point on which they were unanimous was, therefore, that given a correct *x*-ray diagnosis of giant-cell tumour the treatment should be by *x* rays. The second point was that *x*-ray therapy and local surgery, including the taking of a biopsy, should never under any circumstances be combined, since the two together were liable to make the tumour malignant. I saw such a case in Northampton a year ago. Dr. Haagensen thinks the extreme vascularity of these tumours

is the reason for this danger. If a biopsy is indicated then surgery is the only treatment to be considered, whatever the result of the biopsy. In such cases a quick frozen section at the time of operation is of the utmost value in many cases; the nature of the lesion may be obvious from it and the appropriate treatment can be given with the patient still under the anaesthetic. At the Presbyterian Hospital avertin and gas and oxygen is the routine anaesthetic for these cases; its value while the diagnosis is being discussed is obvious.

If the frozen section leaves doubt as to the nature of the tumour, what is the correct procedure? Some are emphatic that the case should be immediately treated as if it was malignant, because there is danger of metastases while routine sections are prepared. Dr. Haagensen and many others, in quoting the results of observations on something like 30,000 cases, are more emphatic that no deliberate treatment should be undertaken while the diagnosis is uncertain, and that there is no danger whatsoever in waiting a week for perfect sections. Such a statement is contrary to the surgical principles on which we were reared, but it does seem that the evidence in support of it now forthcoming from the United States is so overwhelming that we are arriving at a point at which it is useless to deny its truth any longer.

The second point on which there is a difference of opinion is in the 5 per cent. of cases in which the tumour was malignant from the start. In these cases amputation is the operation of choice. Most of the patients who have recovered have been so treated. It is admitted to be better than *x*-ray therapy, but how much better? The American Registry certainly has records of a few five-year cures, but the chances of success are so remote as to be almost negligible. The Presbyterian Hospital so far has had no cures in these cases. The practical point then is this: if a patient has a femoral tumour which an experienced radiologist thinks is a giant-cell tumour, should he take the 95 per cent. chance of an ideal result with practically no loss of work which modern *x*-ray therapy offers? Or should he suffer at the hands of the surgeon for fear that he is one of the 5 per cent. of cases in which the radiologist is wrong. Then, if he is in that 5 per cent., what prospects does amputation hold for him? Let us not deceive ourselves: it is death almost as surely as if he had tuberculous meningitis.

If I am ever in such a position I can assure Mr. Harry Platt that I will not even think of the treatment he advises, and if I prove to be in the unfortunate 5 per cent. I will not take an action against the radiologist, but die in the belief that death was inevitable. The view that these cases should be all treated surgically is opposed by that of such surgeons as Drs. Allen Whipple, Hugh Auchincloss, Cushmann Haagensen, and many others with an enormous experience. Most of the confused ideas have resulted from ignorance of the *x*-ray appearance of giant-cell tumours undergoing treatment by radiation, thus leading to the dangerous mixture of the two forms of treatment. (The senior radiologist at the Presbyterian Hospital was on holiday when the *x*-ray was taken which led to the amputation of the limb mentioned previously.)

My own experience of these cases is naturally very limited, but such as it is it is entirely in accord with Dr. Haagensen's teaching. Because correct treatment can cure these tumours the subject is one of enormous importance and a definite procedure should be established.—I am, etc.,

G. R. OSBORN,
Pathologist, Derbyshire Royal Infirmary.

Aug. 7.

Elongation and Dilatation of the Colon

SIR,—I should like to corroborate some of the remarks made by Professor Learmonth in his address on elongation and dilatation of the colon (*Journal*, July 24, p. 154). In my experience lumbar sympathectomy can be relied on to produce dramatic improvement in all cases of true Hirschsprung's disease. Moreover, the improvement appears to be permanent. I have two patients who were operated on ten years ago, and their bowel function remains perfect. In both these cases a barium enema still shows a grossly dilated colon as large, or almost as large, as before the operation. On the other hand the *x*-ray appearances of the colon after a barium meal are normal.

Like Professor Learmonth, I have no faith in sympathectomy as a cure for intractable constipation. I have tried the effect of this operation in ten cases. Seven showed no improvement, three cases showed temporary improvement, but as time went on all of them relapsed into as bad a state as before operation. I am aware that from time to time successful results have been published—I have myself reported such a case—but I am more and more convinced that these results are due to improved dieting and not to the operation.

I have tried at one time or another many methods of depriving the distal colon of its inhibitory nerves, and agree that Telford and Stopford's operation is the most eclectic and therefore the most desirable. I prefer, however, an extraperitoneal approach to the sympathetic cords, and use an oblique incision in the position and direction of McBurney's incision for appendicectomy. The muscles of the abdominal wall are split in the direction of their fibres and the peritoneum is retracted inwards, exposing the sympathetic cord. Spinal anaesthesia greatly facilitates the operation, which is a minor procedure taking no more than fifteen minutes. The convalescence is quite uneventful; the patient can be up in five to seven days and go home a few days later.—I am, etc.,

J. B. OLDHAM.

Liverpool, Aug. 6.

SIR,—While in agreement with the substance of the letter by Mr. D. Ligat and Dr. T. D. Overend in the *Journal* of August 7 (p. 293), I wish to correct its reference to myself. The writers say, "without agreeing with Mr. Slesinger (*Lancet*, 1926, **2**, 274) that dolichosigmoid forms in itself a sufficient indication for colectomy, we must maintain . . ." and so impute to me the unholy desire of removing every pelvic colon which exceeds its normal length! I need hardly say that such misguided surgical enthusiasm was never mine, and if I may quote from my original paper on the matter my views will, I think, become clear. I wrote: "The pelvic colon varies in length between considerable limits in perfectly healthy individuals, and is relatively much longer in the infant than in the adult. The following remarks are therefore not intended to suggest that elongation of the pelvic colon necessarily results in the production of symptoms, but rather to point out that in certain cases such elongation produces results sufficiently severe to call for relief. . . ."

In the eleven years since that paper was written I have performed the operation of excision of the pelvic colon for dolichosigmoid twenty times, a record hardly suggesting that I think that "dolichosigmoid forms in itself an indication for colectomy."—I am, etc.,

E. G. SLESINGER.

London, Aug. 9.

Treatment of Enuresis

SIR,—I read with interest the article by Dr. Robert Hutchison in your issue of July 31 (p. 206). The fact that enuresis is mostly nocturnal and the result of vagotonia suggests some allergic significance. In the young vagotonic tolerance is low. In many cases fear will induce decontrol of the sphincters of both bladder and rectum; it can thus readily be inferred that allergic children will show a greater tendency to enuresis. Bray (1934) points out that he has successfully treated cases on this assumption. The value of treatment by belladonna and ephedrine also suggests a close alliance with allergic diseases such as asthma, in which vagotonic inhibition is low.

As organic stimuli in the majority of cases can be excluded (Hutchison, 1937), psychological effects must be considered. Dr. R. G. Gordon (1937) maintains that organic factors, if present, simply loosen the higher centre controls. In sleep the conscious mind is out of action, but the unconscious continues to operate in the form of *dreams. Dreams are a medley of repressed memories* (Hart, 1930). Dreams of grief are likely to break through any weakness in the inhibitory barrier, and stimulate the corresponding vagotonic centre. Psychological factors in vague rheumatism also show a striking analogy (Halliday, 1937). If this process be mitigated, then it is possible that inhibition will be strengthened. Belladonna depresses vagotonia; ephedrine modifies vagus activity by stimulating the antagonistic properties of the sympathetic. Therefore, cessation of enuresis, however produced, will tend to eliminate egocentricity and at the same time repress the potency of the grief. Witness the happy expression of the child that has just passed an uneventful night. In order to produce inhibition drugs are first tried; psychotherapy may be helpful in older children and in adults, but a suitable psychological atmosphere must be created. Parents should evince no distress nor adopt any unfavourable attitude, and allergic tendencies should be investigated. Climatological factors should be dealt with by consideration of general health improvement in the light of Kestner's (1937) researches. He gives an admirable scientific discussion of the mental and physical benefits of fresh air. The following case may be of interest.

A young man, aged 25, had suffered from enuresis and faecal incontinence (both nocturnal) since childhood. Bromides and belladonna plus the treatment of haemorrhoids cured his faecal incontinence, but enuresis persisted. Unfortunately—or fortunately—he discontinued medical treatment. Some months later I met him and inquired about his condition. With a cynical grin he told me that a glass or more of beer at night had "completely chased his bed-wetting." In other words, he had succeeded in "drowning his sorrows."

Although I was impressed, I have not yet felt sufficiently heroic to prescribe this treatment.—I am, etc.,

Birmingham, Aug. 7. A. W. DOCKAR.

SIR,—Dr. Robert Hutchison's comprehensive paper on enuresis (*Journal*, July 31, p. 206), following closely on the interesting correspondence on that subject, adds considerably to our knowledge of the treatment of this distressing complaint. There are nevertheless one or two omissions. The first is that enuresis is usually familial. The second concerns diet. A bland non-nitrogenous diet is the most successful, and of course milk should be substituted for tea or coffee. The best therapeutic agents are undoubtedly belladonna and the bromides. However, calcium lactate with vitamin D and parathyroid will often be found successful even in the most obstinate case. With regard to ephedrine, the only occasion on which I used it I found it made the child restless and unable to sleep.—I am, etc.,

Spinal Tumours

SIR,—The editorial article on the subject of spinal tumours (*Journal*, July 31, p. 220) is of much interest, but it loses in value because of its failure to take account of, or to give credit to, the pioneer work of Sir William Macewen of Glasgow on the surgery of the spinal cord. It should not be forgotten that, before Horsley and Ballance had carried out their initial operation in London, Macewen had already a solid record of successful spinal surgery behind him. In addition to this, he first in all the world gave evidence, as early as the year 1876, of the possibility of making accurate diagnoses of lesions of the central nervous system from physiological localizing signs alone.[1]

Horsley's operation was carried out in 1887; but in the years between 1883 and 1886, before Horsley was appointed surgeon to the Queen Square Hospital, Macewen reported five cases in which laminectomy had been performed for paraplegia caused by pressure, due in some instances to granulomatous tumours, on the spinal cord. By 1888 he had to his credit six cases in which the posterior arches of certain vertebrae had been removed. Four of the patients concerned made complete recoveries; one died several months after operation from the effects of advanced tuberculosis; while in the case of the sixth death was possibly hastened by operative intervention—or, at least, such was Macewen's own opinion.[2] It was Macewen's misfortune, if indeed one may look upon it in such a light, that in this period no actual neoplasm (in the strict sense of the term) of the spinal cord was encountered by him; but this circumstance, so similar to that concerned with his work on the brain, in no way detracts from his priority of achievement.

The unfriendly atmosphere in which he commenced his work on the spinal cord was amply described by Macewen at the historic Glasgow meeting of 1888.

"The spinal membranes and the cord itself," he said, "can be exposed, and neoplasms and encroachments on the lumen of the canal may be removed therefrom without unduly hazarding life. Such interference is unsparingly condemned by writers on the subject, their remarks, however, being applied to injuries, as no such operations have hitherto been contemplated in idiopathic cases. They contend that they are full of danger, being difficult, prolonged, and attended by profuse haemorrhage; secondly, that operation could hardly benefit the patient; and, thirdly, that no one has as yet been able to present a successful case. Each of these points has now lost its validity. The first operations of this kind were undertaken by me for the relief of paraplegia due to angular curvature of the spine. In such cases pressure may be exerted on the cord either by connective tissue neoplasms or by direct displacement of the bodies of the vertebrae, both lessening the lumen of the canal."[3]

At the Glasgow meeting of 1888, possibly remembering the want of recognition accorded to his work on the occasion of the presentation of the record of the Godlee-

[1] Macewen. *Pyogenic Diseases*, p. 189.
[2] —— (1888). *British Medical Journal*, 2, 302.

Bennett case of a cerebral tumour in 1885, Macewen himself laid claim to priority in the field of spinal cord surgery, and he could not be gainsaid. Referring to his operative treatment, he remarked: "Such operations are now beginning to be practised by others. Mr. Horsley has a few months ago published the account of a successful case, in which a somewhat similar operation has been performed for the removal of a small tumour of the theca, diagnosed by Mr. Gowers."

It is but just that the work of a very great originator should not thus early be forgotten.—I am, etc.,

Dalmellington, Aug. 3. A. K. Bowman.

*** We would not for one moment detract from the honour due to that great pioneer of the surgery of the central nervous system, Sir William Macewen, but our leading article was concerned not with the surgery of the spinal cord but with spinal tumours and the first removal of a spinal tumour. For this there appears to be no doubt that Horsley was responsible, and the credit must be his. It may have been, as Dr. Bowman points out, Macewen's misfortune that in his early laminectomies he did not encounter an actual neoplasm, but so it was with others. In 1873 E. Leyden of Strasbourg (*Klinik der Rückenmarks-Krankheiten*, Berlin, 1874, **1**, 467) diagnosed and localized a spinal tumour, subsequently verified at necropsy, upon which he had proposed operating but was prevented from doing so.—Ed., *B.M.J.*

Impacted Ureteral Calculus

Sir,—As perhaps indicating the value of expectant rather than operative treatment in cases of impacted ureteral calculus in which the patient is not a good subject for operative treatment, the following case may be of some interest.

In May, 1929, the patient had an attack of renal colic and consulted the late Mr. Frank Kidd. A radiograph showed the calculus to be impacted in the left ureter about one and a half inches from the bladder. The patient was 60 years of age, and although an otherwise healthy man weighed 16 stone. Mr. Kidd recommended no active treatment other than an occasional injection of morphine and atropine to relieve any ureteral spasm. He offered to oil the stone *in situ*, but was not very enthusiastic as to its beneficial effect; he gave it as his opinion that the stone would sooner or later complete its journey, and that so long as it gave rise to no untoward symptoms it was better left alone. Mr. Kidd saw the patient twice in the next two years, the stone remaining unmoved during that time and giving rise to no symptoms. An *x*-ray examination has been carried out once a year since with similar findings. Once only, about four years ago, has he had any inconvenience at all, and then only a colicky pain lasting a short time and relieved at once by an injection of morphine and atropine. On the morning of August 7, on rising, he passed the calculus, more than eight years after its impaction.

—I am, etc.,

Darlington, Aug. 7. J. W. Astley Cooper.

Tests of Renal Function

Sir,—May I make a few comments on Dr. C. S. D. Don's article (*Journal*, July 10, p. 54) and on Dr. N. Lissimore's letter (July 31, p. 244)? In estimating renal function there are two things to be noted: in the first place, Is there a lesion present; and, secondly, What is the function of the kidney as a whole? To my mind the best test for the detection of a renal lesion is the concentration test following the technique described by Calvert of Belfast. It corresponds to the exercise tolerance test employed by the cardiologists, in that it tries to find out how the kidney will react to increased work. The Van Slyke urea clearance test, on the other hand, gives a much truer picture of the kidney as a whole and as to how it is fulfilling its function in the body. Owing chiefly to the brilliant work of Richards the tremendous amount of reserve the kidney possesses is now realized; a lesion may be present and yet the kidney function under normal conditions may be perfect.

As I remarked in the *Ulster Medical Journal* of January, 1937, the blood is the environment in which the kidney works and the urine is the result of its labours, and so both must be taken into consideration when examining renal function. The urea clearance test does what no other renal function test does, it considers the three essential factors in renal activity—the blood urea, urine urea, and the volume of urine excreted in unit time. It is thus theoretically the best test of kidney function, and I think this is borne out by every one who has given the test a fair trial. A short time ago a boy was seen with a history of tonsillitis followed by acute nephritis several months previously, and tonsillectomy was now being considered. The kidneys were unable to concentrate or dilute properly, but the urea clearance test was normal. This was pointed out to me as a case in which this test had failed. Is it not more rational to say that the renal lesion, which was obviously present both clinically and as shown by some degree of fixation in specific gravity, was not handicapping the kidney, which, as shown by the clearance test, was still doing its duty properly? That is, the kidney had compensated. This was borne out by the after-history of the patient.

If this interpretation is granted, then there are two corollaries. In the first place, in the estimation of renal function no one test should be relied on but rather the whole picture studied. The urea clearance test is intended to supplement other tests, not to replace them. Secondly, in the evaluation of the urea clearance test it is not enough just to compare it with the results of other tests. Its true value is only shown by a careful follow-up of the after-histories of patients and of their clinical condition as compared with the results of the clearance test. —I am, etc.,

Harrogate, Aug. 4. J. V. Wilson.

Abuse of Caesarean Section

Sir,—Mr. Malcolm Donaldson's letter in the *Journal* of July 31 (p. 243) in reference to Caesarean section is indeed timely in view of the deplorable fact that it is becoming an operation too often resorted to in preference to other methods of delivery which have stood the test of time and proved perfectly adequate in cases for which section is now being indiscriminately advocated. As he truly says, the operation itself is simple. It is not attended by the difficulties ascribed to it by the lay mind, with the unfortunate result that the false impression entertained by the public may, and probably does, tempt many to practise what adds to their professional reputation and income without due consideration being given to the needs of each individual case, and the best and safest way of meeting them. Mr. Donaldson will have conferred a benefit upon all would-be mothers if his warning based upon such wide and enlightened experience succeeds, as it should, in putting all enthusiasts on their guard against what may and does constitute an added danger to the risks of child bearing.—I am, etc.,

Greenhithe, Kent, July 31. D. W. Standley.

The Normal Female Pelvis

SIR,—Many practitioners will welcome the article by Dr. H. Thoms in the *Journal* of July 31 (p. 210); it is one of the first in this country to try to correlate the findings of accurate pelvimetry with practical experience in obstetrics. Nevertheless measurements of primiparae in England give different results from those obtained by Dr. Thoms in America, and do not substantiate his claim that the "mesatipellic" type rather than the "brachypellic" type is the normal pelvis in white women. I have analysed a series of 300 pelvimetric measurements in accordance with Dr. Thoms's classification, with the following result:

	Dolichopellic	Mesatipellic	Brachypellic	Platypellic
Dr. Thoms: 450 cases	15 per cent.	45 per cent.	35 per cent.	5 per cent.
Moreton District Hospital: 300 cases	7 „	26 „	54 „	13 „

In England, then, the brachypellic type is still the "normal" pelvis. Moreover, the averages for the two main measurements in my series are: conjugate, 11.5 cm., and transverse 13.5 cm.—and anatomy textbooks give the conjugate as 11 cm., the transverse as 13.5 cm. These figures, which must have been arrived at after a very great number of measurements on the cadaver, have never been challenged. Dr. Thoms does not give average measurements, but it is not hard to estimate from his paper that the conjugate diameter averages 12 cm. in America, and that the transverse diameter is, on the average, less than 13 cm. Where the measurements in two peoples of common stock like the Americans and ourselves show such large variation, it seems to be impossible to define the "normal" female pelvis more closely than by saying that it is that pelvis which will support the weight of her trunk on her legs and give passage to a full-sized child at term.—I am, etc.,

Moreton-in-Marsh, Glos., Aug. 1. CLARK NICHOLSON.

When to Operate in Appendicitis

SIR,—Even a general practitioner finds the answer to Mr. R. Rutherford's letter (*Journal*, July 31, p. 244) fairly easy. The Ochsner-Sherren expectant treatment of appendicitis cannot possibly be carried out properly save in the immediate neighbourhood of an operating theatre and a first-class surgeon. The reason for this is that in a few cases spreading peritonitis may at any moment necessitate an appendicectomy which is likely to be a difficult one. If this relatively uncommon complication arises in the patient's home during the night the following risks occur: (1) the relations, or even the nurse, will value the doctor's rest more highly than they should, and not send at once; (2) a difficult operation under bad conditions, or a bumpy ambulance journey with an ill patient, may be necessary; (3) some—and probably several—hours' delay will take place when every hour is of the utmost value.

I consider it dangerous to teach this method to undergraduates, some of whom will inevitably misapply it. The simple and uniform rule—attempt removal when diagnosed—is nearly as safe, and the Ochsner-Sherren method should be taught only to the postgraduate with surgical leanings.—I am, etc.,

Woodford Green, July 31. E. B. GREGONO.

Treatment of Laryngeal Diphtheria

SIR,—When I was in practice as a superintendent of a fever hospital I obtained a considerable experience of both tracheotomy and intubation. It was with great interest therefore that I read Dr. A. Gardner Robb's paper in the *Journal* of August 7 (p. 264). I agree with him that intubation is the operation of choice—that is, in hospital practice but not in private practice. As regards instruments, I came to the conclusion that Moreau's modification of Bayeux's tubes and introducer were the best. Dr. Robb does not mention these. Bayeux's instruments were a modification of O'Dwyer's. I am under the impression, however, that in several of the large fever hospitals aspiration has taken the place of intubation.

Dr. Robb asks for information on the subject. May I be allowed to refer him to my book (*A Textbook of Infectious Diseases*, p. 204), in which he will find some statistics, though they are not so extensive as his. Statistics on this subject that can be fairly compared are not easy to obtain. May I also refer Dr. Robb to a paper published in the *Edinburgh Medical Journal* for March, 1902.—I am, etc.,

Hemingford Abbots, Hunts, Aug. 9. E. W. GOODALL.

Anaesthesia in General Practice

SIR,—I am following with great interest the series of articles on this subject. I notice that Dr. Blomfield (*Journal*, July 24, p. 175), in discussing basal narcotics' states that "pernocton . . . never found great favour . . ." in this country. In my experience this drug has given complete satisfaction. I have used it regularly in quite a large number of cases for a period of nearly three years. It has the advantage of requiring no previous preparation of the patient and is simple to administer. A natural sleep is induced with a dose of 4 c.cm. for a normal adult almost before the needle is withdrawn, and the patient never remembers anything of the journey to the theatre or the subsequent administration of ether or gas and oxygen. There are no unpleasant after-effects, and it materially lessens the amount of ether necessary when the latter is used. It may be that I have been fortunate and that I have yet to meet some of the "snags." If there are any I will be very pleased to hear of them.—I am, etc.,

H. GARNER-EVANS, M.B.

Wellingborough, Northants, Aug. 4.

Universities and Colleges

UNIVERSITY OF LONDON

Owen William Roberts, M.D., M.S., F.R.C.S., has passed in the examination for the External Diploma in Public Administration.

UNIVERSITY OF DURHAM

Under the new statutes for the University of Durham, made in pursuance of the Act of 1935, the King in Council has appointed Professor James Fitzjames Duff to be Warden of the Durham Colleges, and Lord Eustace Percy to be Rector of King's College, Newcastle-upon-Tyne. Both appointments will take effect on September 6.

Obituary

EDWIN SMITH, M.D.

Coroner for the Western District of London

We regret to announce that Dr. Edwin Smith, Coroner for West London, died at the age of 66 on August 9, after a long illness.

The only son of Mr. Edwin Smith, of the Inland Revenue, he was born at Melton Mowbray, and was educated at Perth Academy and the Dundee High School. Dr. Smith received his medical training at St. Thomas's Hospital, where he had a distinguished career, being Entrance Science Scholar, William Tite Scholar, Treasurer's Gold Medallist, and, later, house-surgeon. He qualified M.R.C.S., L.R.C.P. in 1892, took the London M.B. with honours in 1894, and the M.D. in 1895. In 1908 he was called to the Bar by the Middle Temple. For some years Dr. Smith was the London University Lecturer in Forensic Medicine and Toxicology to his old hospital, and also examined in forensic medicine at Oxford University. Before being appointed Coroner for West London, he was Deputy Coroner for Westminster and South-West London. He contributed articles on medico-legal subjects to the *Practitioner's Encyclopaedia of Medicine and Surgery*, and the section on medico-legal problems in Fairbairn's *Practitioners Encyclopaedia of Midwifery and Diseases of Women*.

Edwin Smith was a man of strong convictions and, on occasions, outspoken in his criticisms of the profession to which he belonged; his comments a few years ago on the home treatment of insurance patients gave rise to a storm of protest. Characteristic of him was his remark on a man afflicted with an incurable disease who had committed suicide: "This man did for himself what any man would have done for a dog." "Suicide," he said on another occasion, "is the only enterprise where, if you succeed, you are called insane. If you fail you are supposed to be sane." It is not surprising that he held the view that a strong case could be made out for the use of the lethal chamber for those undergoing prolonged suffering incapable of relief. As a result of his experience as coroner he was a firm advocate of safer roads, and had little patience with those whose carelessness exposed themselves and others to danger, deploring the fact that cyclists were not made to carry rear lamps.

Dr. Smith was a man of many interests, chief among which were music and magic. A contribution of his to the *Musical Times* was entitled "On Faulty Sensations of Musical Pitch, with Notes of a Personal Experience." He was a member, and chairman of the council, of the Magic Circle, and himself invented a number of tricks, the best known of which was the "E.S. ring and rod."

Dr. Smith in 1910 married Edith Catherine, daughter of Mr. H. D. Dyer, and had one son and two daughters.

Mr. S. INGLEBY ODDIE, Coroner for Central London, writes: Dr. Edwin Smith came to me some seventeen years ago to ask if he might make a study of Coroners' Law and procedure in my courts, as he was deeply interested in medico-legal subjects and was a member of the Bar. He was at that time in a busy general practice in South London, but he found time to attend my office and courts almost daily for some months, and quickly mastered the details of practice in the Coroner's Court. When a vacancy arose I was glad to appoint him my deputy, and he served in that office efficiently and well until he obtained the appointment of Coroner for North-East London, and later, in 1930, for West London.

Edwin Smith was a shrewd and highly intelligent man, and this, coupled with a kindly and sympathetic nature, made him a very competent and useful coroner, and although he had no practical experience of the law his years spent in general practice as a doctor proved far more useful to him when dealing with the mass of medical problems which came before him every day. He carried on his work quietly, carefully, and expeditiously, and did not pander to the sensational press, seeking rather to get to the root of the matter, to abolish suspicion where there was no real ground for it, to ease the burden of distress which falls on the relatives, and to arrive at the truth.

His personality was unusual, for he played no games, was practically a teetotaller, was a non-smoker, and apparently took no exercise and but little holiday. He was happy, however, in the possession of two hobbies—music and conjuring—and he had an ideal home life. His children and his wife shared his musical enthusiasm, and all played either the violin, the piano, or both, and he often spoke of the pleasure he got from his family orchestra. He was a brilliant success as a medical student, and in later life exhibited a sound, simple common sense which must have endeared him to his patients and afterwards to those who appeared before him in his courts.

It was characteristic of his kindly nature and thoughtfulness that he should have left instructions that the announcement of his death should not be made until after his cremation, thereby avoiding the fuss and formality which he detested.

Dr. F. TEMPLE GREY writes: In the passing of Edwin Smith both medicine and law have lost a very competent practitioner. After a brilliant scholastic career he went into general practice, where he gained a knowledge of men and medicine which made it difficult for a medical witness to theorize overmuch; his training in the law gave him a firm grasp of the principles on which an impartial inquiry should be conducted. His shrewdness made his work of great value to the State, and his advice was sought by many. Like so many outstanding men he was very approachable, for he combined with thorough efficiency a charming personality—a combination rare enough to make his passing a matter of regret to the State and of grief to his friends. His friends—and he had many—will miss him sorely.

REGINALD FRANCIS JOWERS, F.R.C.S.

Consulting Surgeon, Royal Sussex County Hospital, Brighton

We regret to announce the death on August 7 of Mr. Reginald Francis Jowers, consulting surgeon to the Royal Sussex County Hospital and the Victoria Hospital, Lewes.

Mr. Jowers, the second son of the late Mr F. W. Jowers, F.R.C.S., qualified L.S.A. in 1885, M.R.C.S. and L.R.C.P. in 1886, and was elected F.R.C.S. in 1888. He received his medical education at St. Bartholomew's Hospital, where he held the posts of house-surgeon and

resident obstetrical officer. Subsequently he was resident clinical assistant at the East London Hospital for Children. For the following appreciation and account of his career we are indebted to Mr. Hugh N. Fletcher.

For many years Mr. Reginald F. Jowers was an outstanding figure in Sussex, and was known not only as a surgeon whose exceptional skill was sought far and wide, but as a man of great charm and character. After Winchester and St. Bart's days he became house-surgeon to the Royal Sussex County Hospital, Brighton. In 1889 he was appointed honorary assistant surgeon and in 1901 honorary surgeon to the hospital, an active connexion which lasted until his retirement under the time limit in 1921, when he became consulting surgeon. He was also honorary surgeon to the Victoria Hospital, Lewes, and to King Edward VII Hospital, Haywards Heath, for some years. During the war he was a member "à la suite" of the 2nd Eastern General Hospital and served with the rank of lieutenant-colonel. He had been a member of the British Medical Association since 1889, and acted as Vice-President of the Section of Surgery when the Association met at Brighton in 1913. Throughout its long history the Royal Sussex County Hospital has never had a more devoted servant, or one whose work brought to it greater distinction.

Jowers was a big man in every sense of the word. Tall of figure and of handsome presence, his keen and vigorous personality gave a sense of power wherever he went, and when one watched him at work this impression deepened. Every problem of diagnosis and treatment was met, not only with wide knowledge, but with a rare common sense and wisdom which rarely allowed him to go astray. For a man so busy it was remarkable how deeply he read. Everything that could be of future use was stored in a retentive memory and annotated and filed in his records. Jowers's chief characteristics as an operator were courage, decision, and an almost uncanny judgement of what best to do under difficult circumstances. It was perhaps this quality of sound judgement which gained him so fully the trust of his colleagues. Not apparently a quick operator, he nevertheless got through an enormous amount of work in an afternoon and seemed never to tire. The high standard that he demanded of himself he also required in others, and no slackness of any kind was allowed to pass. Duty was to Jowers a watchword which was never broken under any circumstances, and his example in this respect must have been an enduring inspiration to many generations of house-surgeons who worked for him. He hated sham and insincerity and incompetence, and was sometimes very outspoken, but always with the courage of his convictions. None the less, he had the kindest of hearts, and one of the happiest traits in his character was his love of children.

In his prime, and his prime seemed to last right up to the time of his retirement, Jowers's reputation brought him work which must have taxed his strength to the utmost. He was trusted implicitly by doctors and patients alike, and few have more richly deserved such confidence. Indeed, overwork probably brought on the distressing illness which clouded the last few years of his life. Suddenly, soon after his retirement from practice, when he was looking forward to more leisure and to the enjoyment of the sports dear to his heart, he was struck down by subacute combined degeneration of the spinal cord. Some of us wondered how such an ardent temperament would face the disappointment and inaction which such an illness meant. But it brought out a greatness of spirit and a courage which was the more poignant because one knew the self-discipline which it must have entailed.

And so has passed one whose memory will be cherished by many a staunch friend, and a true man who greatly served his time and generation. He will be especially missed by those who were privileged to know him in his home, or to share in those country pursuits, fishing, shooting, and golf, which he enjoyed with such light-hearted, almost boyish, enthusiasm. To his family, and especially to his widow, whose constant and unselfish devotion sweetened the lot of a sorely tried spirit and softened the hardship of long suffering, the thoughts and sympathy of all will go out.

Medical News

The annual dinner of the Chartered Society of Massage and Medical Gymnastics will be held at the Café Royal, Regent Street, on Wednesday, September 22, at 7.30 p.m.

The second International Congress of Gastro-enterology will be held in Paris from September 13 to 15, on the occasion of the World Exhibition, under the presidency of Professor Pierre Duval. The following subjects will be discussed: (1) early diagnosis of gastric cancer; (2) acute and chronic obstruction of the small intestine. The Paris congress will be followed on September 16 by an International Congress of Hepatic Insufficiency at Vichy under the presidency of Professor Loeper of Paris.

The twenty-first International Congress on Alcoholism will be held at Warsaw from September 12 to 17. Particulars can be obtained from the honorary secretary, 33, Bedford Place, Russell Square, London, W.C.1.

Notice is given in the *London Gazette* of July 30 that a petition of the Dean and the Chairman of the Council of the London (Royal Free Hospital) School of Medicine for Women, praying for the grant of a Charter of Incorporation to the school, has been presented to His Majesty in Council; and, His Majesty having referred the petition to a committee of the Lords of the Council, all petitions for or against such grant should be delivered at the Privy Council Office on or before August 31.

The National Advisory Council and the Grants Committee for Physical Training and Recreation issued on Thursday a booklet called *National Fitness—The First Steps* (H.M. Stationery Office, price 2d.). It is primarily intended for the use of local authorities and voluntary organizations, but the Council hopes it will be of interest to the public as well. This discusses briefly the objects in view in the campaign for national fitness, and many possible methods of promoting them. The powers of local authorities are indicated and the extent of the grants which may be made towards the capital cost of approved schemes. The grants will vary from 25 to 75 per cent. of the accepted estimate of costs according to local needs and economic circumstances, but do not provide for aid in maintenance except in cases of special hardship. The booklet lists finally many of the national voluntary organizations interested in the campaign, and the twenty-two Area Committees which are being set up in connexion with it.

The King has reappointed Dr. V. W. T. McGusty, O.B.E., to be a Member of the Executive Council of the Colony of Fiji for a further period.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1., on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.* SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Vaccine Reactions

"RURAL G.P." writes: A patient suffering from chronic catarrh was given an autogenous pneumococcal vaccine at intervals from January to the middle of March. She was persistently overdosed, and an exacerbation in the form of very severe headache, at times one-sided, accompanied by an urticarial type of facial rash, has persisted since the last dose of vaccine. Treatment by glucose, calcium gluconate, and whole blood injections has had no effect. Is the condition a permanent one? If not, how long can it be expected to last, treated or untreated?

Parathyroid Secretion

Major W. GUYON RICHARDS (London, W.1) writes: In the interesting article on parathyroid secretion in the *Journal* of May 1 (p. 929) it is stated that since parathyroid extract is destroyed in the alimentary canal it is therefore worthless when given by mouth. This is not my experience, and my practice is to give an indicated drug with the glandular preparation. Some years ago, when practising at Burgess Hill, we had a considerable number of cases of varicose ulcers of the legs, which were treated by simple dressing and parathyroid extract given orally. The results were excellent, in marked contrast to those obtained before the parathyroid extract was given. There was no need to give calcium, as our water supply contained this in abundance, and the parathyroid fixed it in the tissues. Is not the word "destroyed" a wrong one to use in this connexion, surely "changed" would be more correct? Parathyroid extract given by the mouth can be a valuable addition to other treatment, and is even effective when used alone under conditions like those at Burgess Hill. Possibly with a needed addition it acts as a catalyst. Injection may be more efficient, although in some hands it is risky, but in cases in which it is not feasible it is certainly possible to obtain results by oral administration.

Irish Medical Folk-lore

Dr. M. G. KIERANS (Co. Monaghan), prompted by Dr. Maguire's note (*Journal*, July 31, p. 252) to the effect that the aetiology of itch was long known to the Irish peasantry, writes: An old lady in County Armagh advised a patient of mine who was anaemic to steep minced liver overnight in cold water and to drink the liquid in the morning. She informed him that she had cured her own daughter of anaemia by this treatment over thirty years previously. I remember a boy, thirty years ago, who was treated for anaemia in a similar manner, raw beef being used instead of raw liver. An Irish scholar recently informed me that Irish manuscripts contain many medical references. This is to be expected in the records of a high civilization, and raises hopes that medicine too will benefit from the revival of Gaelic learning.

Income Tax

Interest on Deposit Receipt

"ALPHA" explains that unknown to him a lady instructed her solicitor to place £200 on deposit. She died on June 22, 1936, and "on October 8, 1936, this deposit . . . with the sum of £29 11s. 9d. interest" was handed over to "Alpha." Is he liable to pay tax on the interest?

** When money is placed on deposit receipt the interest does not arise, and is therefore not liable to tax until it is "uplifted." Apparently this has not yet taken place, or did not take place until after the deposit had been legally transferred to "Alpha." In that case he is liable to account for the tax on the £29 11s. 9d. as being the person entitled to the interest at the time it became liable to assessment.

Depreciation of Radium and Apparatus

"ELEMENT" bought 100 mg. of radium in 1933, the cost of the radium being £1,200 and the cost of the containers, lead safe, instruments, £226. The cost of radium has dropped, and its present value is now, say, £750. Can he claim any deduction for the depreciation?

** There is no general allowance for a wasting asset except for depreciation of plant and machinery by reason of wear and tear. It would probably be held that this does not cover the case of a radium equipment, except possibly as regards the safe and instruments. On the other hand it might reasonably be contended that the use of the radium involves some expenditure of its force, and—on the analogy of a stock of a particular drug—the cost should be spread over the probable effective life of the radium acquired in 1933. That would involve reopening the assessments for 1934-5 and subsequent years. In no case can an allowance be claimed on the ground that the present cost is below the actual cost in 1933.

LETTERS, NOTES, ETC.

Pregnancy Tests in Missed Abortion

Dr. T. D. CULBERT writes: A patient, a multipara aged 44, became pregnant in December, 1936, and this diagnosis was verified by two consultant obstetricians. Early in March there was some uterine bleeding, and after two weeks on morphine and rest in bed this subsided, although she lost a fair amount of blood. Neither foetus nor placenta were passed. In May I was called to see her for a recurrence of the bleeding, and the abdomen was no larger than two months previously. This time it was much less severe, and the patient was soon up and about. I told her I doubted that she was pregnant, and thought that her condition was possibly menopausal. Early in July she brought me a specimen of urine; an Aschheim-Zondek test proved negative. I was called to see the patient on July 23, and found she had passed a complete macerated three-months' abortion. This is the first time I have come across a case of "missed abortion" in which an Aschheim-Zondek test was carried out. The result, a perfectly correct one, was a little misleading in view of the patient's age.

A Safe Milk Supply

The importance of pasteurization for ensuring a safe milk supply is emphasized in a memorandum entitled "The Production, Inspection, and Laboratory Control of Milk," issued by United Dairies, Ltd., 34, Palace Court, London, W.2. Raw milk from tuberculin-tested herds can be, within reason, guaranteed free from tubercle bacilli, but not from those of contagious abortion, which cause undulant fever; from mastitis, which predisposes the animal to become a carrier of the organism that causes septic sore throat; and no herd testing can prevent the contamination of milk during or after drawing with scarlet fever, typhoid, diphtheria, and other germs. "In addition to safety the public have a right to demand a milk that will keep a reasonable time under household conditions. For this we require a pasteurized milk with a comparatively low count of souring organisms. To attain a satisfactory standard in this respect a 'clean milk' is essential for pasteurizing." The importance of proper cleaning and sterilizing of buckets and other utensils used for handling the milk is urged, as well as the need for cleanliness of milkers' hands, overalls, and caps

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

128 Carbon Tetrachloride Poisoning

DERVILLÉE (*J. Méd. Bordeaux*, April 24, 1937, p. 557) states that carbon tetrachloride poisoning is not rare, since this compound is widely used in industry in the manufacture of rubber and varnish, in the composition of fire extinguishers, and as a grease solvent: it is also used extensively by hairdressers. Therapeutically, carbon tetrachloride is employed as an antiseptic, as an anthelmintic, and in dermatology as a lotion. Poisoning depends upon external factors—for instance, insufficient ventilation—and also upon intrinsic factors, such as individual predisposition, chronic alcoholism, and renal or hepatic disease. Carbon tetrachloride most commonly enters the body by the respiratory route, but occasionally also by the alimentary tract and through the skin. Toxic absorption manifests itself in many forms, of which the cerebral is the most serious and the hepato-renal the most usual. In the latter type there is first a period of excitement, then a hepatic stage characterized by vomiting, hepatic pain, and enlargement, and, finally, after a fleeting period of improvement, a renal stage in which there is oliguria and albuminuria. Purely renal forms, in which an acute nephritis of the azotaemic and oedematous type is found, are also met with. In the pulmonary types acute oedema of the lung, due to the decomposition of carbon tetrachloride to phosgene, is present. Cutaneous forms are also found, since carbon tetrachloride may give rise to dermatitis, which in severe cases may go on to necrosis. The prognosis is variable and must be guarded, since it largely depends on the method of exposure and on the degree of individual susceptibility. Treatment is purely symptomatic, and care must be taken to avoid further damage to the liver or kidneys by drugs. Venesection is required when pulmonary oedema is present. Bicarbonate of soda should be administered orally, and hypertonic saline intravenously. Cardiac stimulants may be necessary. In order to prevent poisoning the room should be well ventilated; workers should be examined for lesions of the lungs, liver, or kidney. Alcohol should be prohibited, and less toxic substances should be employed whenever possible. Stabilized carbon tetrachloride should be used in the manufacture of fire extinguishers, and the danger of decomposition in a hot and humid atmosphere not forgotten. The application of therapeutic lotions containing carbon tetrachloride should be performed in well-ventilated rooms, with the face protected to prevent the inhalation of fumes. It is contraindicated as an anthelmintic in patients with hepatic or renal disease, or in alcoholics. The dose should never exceed 2 to 3 c.cm. of the pure drug.

129 Gout

C. G. FINCK (*Brux. méd.*, June 6, 1937, p. 1176) points out that gout is not disappearing, but is manifesting itself in other forms. He found classical symptoms of gout in 60 per cent. of his patients before the war, in 11 per cent. between 1918 and 1922, in 48 per cent. between 1922 and 1931, and in 27 per cent. between 1932 and 1937. He states that the normal ratio of uric acid in the blood corpuscles to that in the plasma is as 2 to 4, and that when this ratio drops to 1 to 8 an acute attack of gout occurs. In 1926 he showed by experimental work that (1) an attack of gout is preceded and accompanied by a progressive change in the vago-sympathetic equilibrium towards hypervagotonia; (2) these changes are accompanied by parallel variations of the acid-base equilibrium in the direction of alkalosis; (3) any factor producing vagotonia or alkalinization may produce an attack; and (4) any agent stimulating the sympathetic nervous system or inhibiting the vagus, or the presence of any acid agent, prevented an attack. The condition may be present without demonstrable clinical symptoms. The intensity of articular manifestations depends on the tone of the autonomic nervous system—for example, in old age when vagotonia is present the condition is less painful than when it occurs in younger persons—and also on the anatomical state of the kidney. Attacks of gout in persons with kidney disease are less characteristic than in those with normal kidneys, because the permeability of the kidney is lowered and the elimination of uric acid is less. Gout may occur in articular attacks which do not present classical symptoms, in extra-articular attacks affecting mesodermal tissue—namely, tendons, fibrous organs, and cartilages—and in visceral manifestations. It is important to diagnose the masked forms. Clinically the gravity of the condition is inversely proportional to the acuteness of its manifestations. The definitely gouty person periodically discharges large quantities of uric acid from his tissues. In the masked form of gout there is a permanent saturation of the tissues with uric acid, and this may result in arterial lesions, such as atheroma and arteritis, by the precipitation of cholesterin and its action on the autonomic nervous system.

130 Hay Fever and Asthma

F. F. FURSTENBERG and L. N. GAY (*Johns Hopk. Hosp. Bull.*, June, 1937, p. 412) have treated 907 patients for hay fever and asthma by injections of pollen extracts and have observed constitutional reactions in 4.9 per cent. of cases during an observation period of six years. These occurred in 11.7 per cent. of private patients and 5.9 per cent. of hospital patients treated with pollen extract. The most important cause was the change from injections of large volumes of a weak extract to that of small volumes of strong extract. Less important causes were the use of over-concentrated extracts, injections at too close intervals, too large an increase in the dose, and too large an initial dose. Patients who were receiving pollen and inhalant extracts together had very few constitutional reactions, and those receiving only inhalant extracts had even fewer.

Surgery

131 Gravel in the Kidney and Ureter

G. MARION (*J. Urol.*, April, 1937, p. 297) records five cases in which gravel in the kidney or ureter caused partial or complete obstruction. It is suggested that post-operative anuria may sometimes be due to obstruction of the renal tubules by crystals which are formed after certain operations on the urinary tract. The formation of gravel in the ureter is usually followed by its spontaneous passage, and this may be unnoticed if the patient possesses both kidneys, but when one has previously been removed anuria may be produced, and two instances of this are described. Gravel in the pelvis of the kidney gives rise to the same symptoms as calculus, and in some cases the gravel fills the whole of the pelvis and calices. Sometimes it is passed as a result of medical treatment: an instance is given of a young girl in whom radiography showed a stone the size of a bean, while an earlier photograph had shown it to be coral-shaped and much larger. It was established that, in the first *x*-ray photograph, what appeared to be a large branching calculus was really gravel which had passed in the interval between the taking of the two photographs. Pyelotomy was later carried out for the removal of the stone. Any variety of lithiasis may give rise to this gravel formation, and in three cases in which the deposit was analysed it was found to consist of oxalates, urates, and phosphates. A correct diagnosis cannot always be made by radiography, but when anuria

is present and no stone can be seen gravel should be suspected. In this case, as when a stone is present, the treatment consists of ureteral catheterization, followed by surgical intervention if the gravel or stone is not passed and the obstruction relieved.

132 **Hallux Valgus**

HENDRIX and KEMPENEERS (*Scalpel*, Liége, May 22, 1937, p. 641), in describing the pathogenesis and treatment of hallux valgus, emphasize the importance of the early treatment of all painful lesions of the foot. Hallux valgus should not be considered only as a local deformity, but also as a symptom of some other condition which would have been curable without recourse to surgical treatment had it been treated in the early stages. In many early cases the condition may be improved by the wearing of a surgical boot. Hallux valgus often develops in an adult who has suffered from rickets in infancy. It may be preceded by valgus of the foot and the presence of scoliosis. There is an external rotation of the foot and leg, with flexion of the knee and of the hip-joint. The lumbar lordosis which results is compensated for by dorsal kyphosis. At this stage an orthopaedic boot may correct the position of the foot, but if no treatment is carried out hallux valgus may develop in adult life. High heels may be contributory factors, as the weight of the body is then thrown forward on to the big toe. Successful treatment must correct the abduction and rotation of the big toe, and bring the others into a correct position; it must draw the first and second metatarsal bones together, re-establish the muscular equilibrium, and correct the flattening of the anterior and longitudinal arch. Hohman's operation alone fulfils all these requirements, and is therefore recommended; the technique is fully described and illustrated.

133 **Surgical Treatment of Typhoid Carriers**

F. A. COLLER and F. C. FORSBECK (*Ann. Surg.*, May, 1937, p. 791) performed cholecystectomy on eighteen chronic biliary typhoid carriers, aged from 15 to 55, of whom fifteen were females and three males. All but two were cured, and no deaths took place. Eligibility for the operation was decided on the patients' being gall-bladder carriers and good surgical risks. A cure was considered to be effective when twelve consecutive negative specimens of the faeces had been obtained, and at least one specimen of negative bile.

134 **Albee's Operation for Spinal Caries**

E. T. CATO (*Austral. New Zeal. J. Surg.*, April, 1937, p. 361) is of the opinion that in the treatment of tuberculosis of the vertebral bodies absolute rest is essential in order to ensure that the lesion heals as quickly as possible. Internal splinting by means of a bone graft used in conjunction with an external apparatus gives more complete fixation than if the internal splint is applied alone. Convalescence is not shortened by the use of the bone graft, but a more extensive and efficient ankylosis is obtained, and the risk of recurrence is lessened. The presence of sinuses and therefore of secondary infection, and the tuberculous involvement of more than a few vertebrae, are contraindications. Abscess formation is an indication for operation, since the increase in fixity of the diseased area assists in shortening the time of absorption. The presence of kyphosis may necessitate an angled graft, or, if the deformity is too acute, the angle of the graft can be increased by multiple cuts on its convexity. The Albee operation has been carried out in preference to that of Hibbs in the thirteen cases reported for several reasons: it is more speedily performed, it produces less shock, there is less likelihood of failure, and fixation is immediate and is obtained before bony union occurs. The technique is fully described. After operation the patient is not moved for ten days, and then only at intervals for examination and attention. Progress is controlled by radiographs taken every three months. The patient is not allowed up for at least six months, or until after all pain, spasm, and tenderness have disappeared and bony union of the graft is evident. A surgical corset is worn for at least another six months. A good result was obtained in every instance.

135 **Putti's Arthrodesis of the Shoulder**

D. LOGROSCINO (*Arch. ital. Chir.*, May, 1937, p. 591), who records seven illustrative cases in patients aged from 4 to 77, states that in the years following the first arthrodesis of the shoulder performed by Albert in 1878 the operation was regarded with scepticism and distrust. However, Putti's method of combined intra- and extra-articular arthrodesis of the shoulder, which he has employed at the Marino di Oltra Hospital, deserves to be widely employed owing to its simplicity and excellent results.

Therapeutics

136 **Formol Toxoid for Staphylococcal Lesions**

G. RAMON *et al.* (*Presse méd.*, June 16, 1937, p. 889) give the results obtained by using formol toxoid in the treatment of various staphylococcal lesions of the skin, particularly that of chronic furunculosis. Details are given of 400 recent cases treated by formol toxoid. Of these the largest number were cases of recent or chronic furunculosis, of which there were 239 instances, and there was complete recovery in all but thirty-four cases, five of which were improved, while the remaining twenty-nine relapsed. Cases of anthrax, acne, staphylococcal adenitis, and sycosis barbae were also treated with good results, the majority of patients being cured or improved. After a test injection to ascertain the allergic reaction of the patient, subcutaneous injections of formol toxoid were given in increasing doses of from 0.25 c.cm. to 2 c.cm. at intervals of a week or less. Good results have also been obtained in other parts of France and in her colonies, but the lack of success in England and America is attributed to the smallness of the dose of formol toxoid administered. This method of treatment has been tried in cases of osteomyelitis and staphylococcal septicaemia, but the results have not been uniformly satisfactory.

137 **Dystrophia Adiposo-genitalis**

P. PLUM (*Ugeskr. Laeg.*, June 17, p. 643) states that since 1930 various tests have been undertaken in the Children's Department of the Rigshospital in Copenhagen on preparations which were claimed to contain hormones calculated to influence the course of dystrophia adiposo-genitalis. The lack of uniformity in the action of these preparations was probably due to the inadequacy of their concentration. More encouraging results were observed during the past half-year; five cases of dystrophia adiposo-genitalis, one of adiposity, and two of cryptorchism were treated with deep intramuscular injections of "physex," which is prepared from the urine of pregnant women and is standardized according to its lutein action on mice. Two of the cases of dystrophia and both those of cryptorchism were treated only with this preparation, while the others were given thyreoidin in addition. The usual dose was 200 mouse units of physex every day for some weeks, and later every other day. This dosage is heroic compared with that of other investigators, and the author's policy has been to achieve a well-marked and rapid action, and thereafter to work down to the optimum and most economic dosage. According to the case histories, photographs, and tables published, this treatment was invariably associated with marked growth of the genitals. Erection was observed in two cases, and in the only case in which spermatozoa were sought in the urine they were found there. This treatment did not affect the basal metabolism or the abnormal distribution of fat, but when it was

supplemented by thyreoidin and an emaciating diet great loss of weight followed rapidly. A boy aged 12, who was suffering from adiposity and a low basal metabolism, but had normally developed genitalia, showed growth of the genitals accompanied by loss of weight when physex and thyreoidin were given. In one of the two cases of cryptorchism associated with adiposity, the treatment was followed in two weeks by the descent of the testicles and by the growth of the genitals. In the other case there was no change in the position of the testicles, but there was a marked growth of the penis after two months' treatment.

Radiology

138 Cardiovascular Complications

H. BARTSCH and G. WACHNER (*Klin. Wschr.*, May 22, 1937, p. 743) describe the effects on the cardiovascular system which they were able to observe in a large proportion of cases of carcinoma of the pharyngo-laryngeal region treated by Coutard's method of protracted and parcelled deep *x*-radiation. The complications were caused by the toxic products of the irradiated tissues, and manifested themselves in myocardial degeneration and disturbances of the cardiac rhythm. The fall of the blood pressure and the acceleration of the pulse may lead to coronary insufficiency in cases predisposed to angina pectoris. The authors therefore advise careful observation of the cardiovascular system and appropriate prophylactic measures in all cases treated by Coutard's method.

139 Prostatic Enlargement

G. H. SCHNEIDER (*Med. Welt*, May 15, 1937, p. 679) ranges himself on the sides of other German writers who have recently praised the *x*-ray treatment of prostatic enlargement, and he reports twenty-four successful cases. Besides avoiding the risks of narcosis and operative trauma, the preservation of sexual function is claimed. The dosage is worked out after pelvimetric measurements of sacro-prostatic, pubo-prostatic, and sacro-pubic saggital distances. The application is in the form of 90 per cent. of the erythema dose to a total of 350 to 500 *r* according to the focal distance chosen; preferably five fields of 10 by 15 cm., one perineal, two parasymphyseal, and two parasacral, are used. Before the benefit of the intensive irradiation is registered and the treatment is repeated (often two months) five or six weekly supplementary "saturation" applications are made, each of 50 to 100 *r*, from large, distant symphyseal or sacral fields. The treatment is to be combined at first with catheterization, and may cause a temporary increase in dysuria. The widespread opinion that advanced cases of prostatic hypertrophy are not radiosensitive is stated to be unfounded.

140 Varying Skin Sensitivity

J. BORAK (*Wien. klin. Wschr.*, May 14, 1937, p. 632) stresses the relative sensitiveness of the different constituent elements of the skin to *x*-radiation. Experiments have proved that the single lethal dose for the sweat glands is about 2,500 *r* units, for the epidermis 2,000 *r* units, for the hair follicles 1,600 *r* units, and for the sebaceous glands 1,200 *r* units. There is also a difference in the latent periods between the application of the rays and the final effect—for example, the sebaceous glands are obliterated three to four weeks after the irradiation, while the sweat glands take three to four months to disappear. This is probably due to the different mechanisms of the cell destruction in each case. The rays act directly on the sebaceous gland, while the sweat glands are obliterated as a result of the damage to their capillary blood vessels. These different actions are explained by the different biological nature of the sebaceous and sweat glands. Sebaceous glands belong to the holocrine glands, while sweat glands belong to the merocrine glands. In the first the secretion is due to a gradual elimination of the cells themselves, while in the second the secretion is only a product of the glandular cells.

141 Cholecystography

E. N. COLLINS and J. C. ROOT (*Clev. clin. Quart.*, April, 1937, p. 85), in an attempt to standardize procedure in the newer developments of cholecystographic examination, point out the following features. It has been found that the administration of multiple doses of the dye produces greater density in the visualized gall-bladder than does a single dose, and it makes non-visualization of greater significance and it does not harm the patient. The administration of large amounts of sugar and other carbohydrates, before and during examination, facilitates the excretion of the dye by the liver. One ounce of a mixture of egg yolk, lecithin, and glycerin is as efficacious in emptying the gall-bladder as the fat meal. The use of pitressin in eliminating confusing shadows in the intestinal tract which lies over the area of the gall-bladder has precluded the necessity for re-examination; it has also made the multiple dose oral method of cholecystography possible on the same day that barium meal examinations of stomach and small intestine, or barium enema examinations of the colon, are made. In a series of 1,250 cholecystographic examinations pitressin was used in 200 cases, and effective results were obtained in 87.5 per cent. of these. In a more recent series, in which the new ampoule containing 20 pressor units was used, effective results were obtained in 90 per cent. of cases. Diagnosis in these cases is usually simple when there is a history of biliary colic, especially if associated with jaundice, and it may be confirmed by cholecystography. In inflammatory diseases of the gall-bladder physical examination is only of assistance during the acute or subacute stages. The authors observe that during the last five years the operative findings have coincided with the cholecystographic either positively or negatively in 95 per cent. of cases.

142 Transnasal Bronchography

G. SCORPATI (*Rass. Clin. Terap.*, March–April, 1937, p. 92) describes the following method of transnasal bronchography which is in use at the out-patient department of the Forlanini Institute at Rome. About forty minutes before bronchography the patient is given an injection of sedasol or some similar preparation, and twenty minutes later, before the administration of novocain anaesthesia, he is made to gargle with the contents of half a glass of water containing 15 to 20 drops of a 1 per cent. solution of heroin. With the patient in a sitting position a rubber tube attached to a syringe containing 8 to 10 c.cm. of a 2.5 per cent. solution of novocain is introduced into the most pervious nostril and the solution injected drop by drop; the patient is told not to swallow but to take deep breaths. He is then placed first on his left and then on his right side so that the fluid can reach the bronchial ramifications in both lungs. After a few minutes' rest the opaque substance is injected slowly. In the large number of cases in which this method was employed no untoward incidents occurred.

143 Encephalography

J. T. TRAVERS (*Radiology*, June, 1937, p. 704) maintains that when the ventricles and subarachnoid spaces are symmetrically filled with air, or when they are both dilated without a ventricular shift, the presence of a subdural haematoma may be excluded. He also notes that in subdural haematoma the ventricular shift is away from the side of the lesion, while in the presence of scar tissue resulting from a laceration of the brain it is usually towards the lesion. As the clinical symptoms of this con-

dition may simulate those of other post-traumatic sequelae, the differential diagnosis is of importance, since surgical treatment is definitely indicated in subdural haematoma, and the earlier the treatment the better the results, while in other cases with similar clinical symptoms surgery may be definitely contraindicated. Encephalography is also of value in the localization of the subdural haematoma, as the signs and symptoms are often confusing. The author has used encephalography in the study of post-traumatic sequelae of brain injuries, chiefly with the object of determining whether or not there was an actual brain lesion to account for the subjective symptoms. He found evidence of this in a large proportion of such cases. Encephalography proved harmless in patients suffering from the sequelae of brain injuries; in a number of cases, excluding those with adhesions or with cortical atrophy, it has even proved beneficial.

144

Spacing of Radiation

J. C. MOTTRAM (*Brit. J. Radiol.*, June, 1937, p. 494) has shown experimentally that tumours are more adversely affected by gamma radiation spaced over a week than by a continuous exposure of 210 minutes. This was due to the fact that the spacing of the radiation was controlled in such a way as to influence the tumours during the periods of active growth and to avoid the periods of inhibited growth which follow radiation. For large doses the spacing should be wide and for small doses narrow; but each type of tumour requires a different spacing if the highest efficiency in treatment is to be obtained. Further research in this direction is still necessary.

Obstetrics and Gynaecology

145

Acute Ulcus Vulvae

A. CROSTI (*Athena*, May, 1937, p. 210) accepts as a clinical entity the occurrence of acute vulval ulceration due to the *B. crassus* of Lipschütz. It is most common in girls or young women, and is not conveyed by coitus. Acute painful ulcerations, which in the majority of cases are gangrenous, affect the vulva, and there is a variable degree of general prostration and pyrexia. The course is invariably benign, but relapses may occur. Diagnosis and aetiology present difficulty. The bacillus of Lipschütz is usually present—often in nearly pure culture. It is cultivable in agar-ascitic fluid and sugary media and produces much lactic acid, but it is easily confused with (and has been said to be the same as) Döderlein's bacillus. The Lipschütz bacillus, however, has been recovered from the blood and from the aphthous oral ulcers which sometimes accompany the vulval ulceration. Of this a subacute form resembling venereal streptobacillary ulceration, and one with small superficial ulcerations, have been described, but are less common than the gangrenous form. A general rash, usually papulo-erythematous or vesicular, but sometimes pustular, may be present, and slight desquamation may follow. Cure is always speedily obtained by weak antiseptic applications and by rest.

146

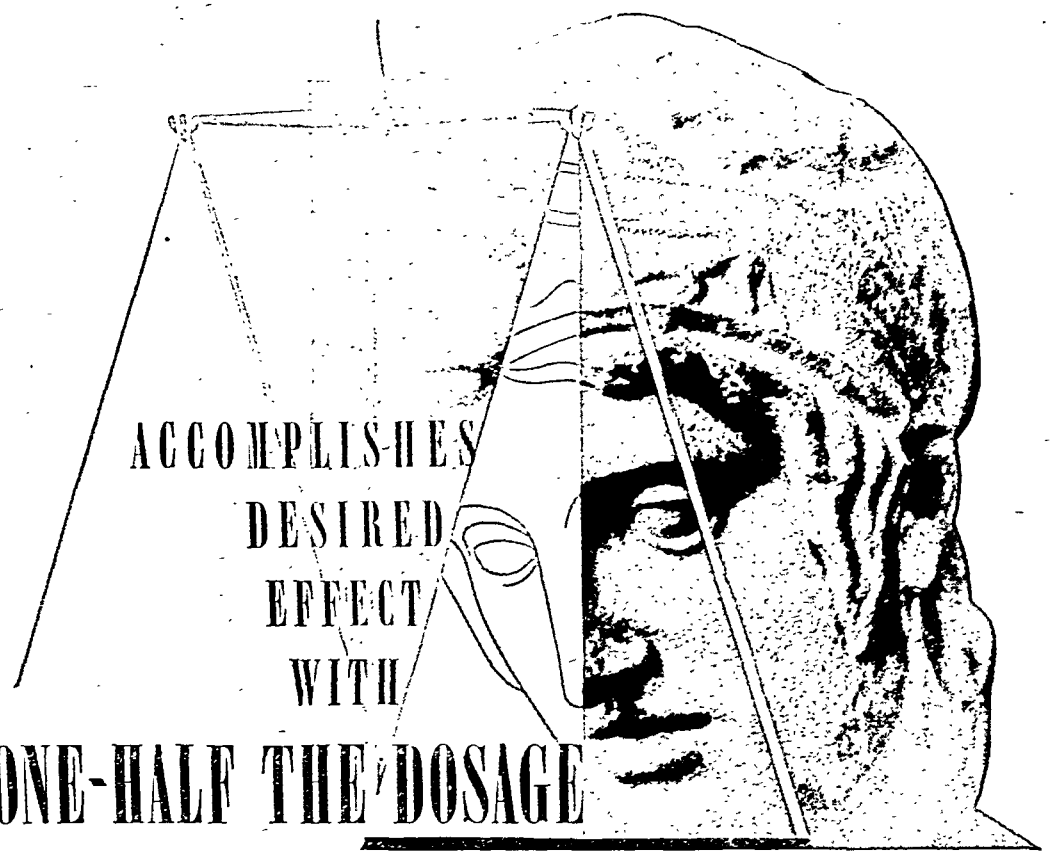
Tetany and Pregnancy

P. MANDRUZZATO (*Ann. Ostet. Ginec.*, April 30, 1937, p. 511) states that although the appearance or aggravation of tetany in connexion with pregnancy or the puerperium is not very common, it is associated with a mortality varying from 5 to 30 per cent., and calculated at 7 per cent. from statistics collected in 1913. In Paris the association is very rare. In Vienna comparatively common. In Trieste two cases have been seen in twelve years; the first showed aggravation of pre-existing tetany during pregnancy, its disappearance after parturition, and no recurrence in a succeeding gestation. The second was associated with acute cyanosis eleven hours after spontaneous labour, and it proved fatal on the same day.

Tetany is favoured in pregnancy by the diminution of blood calcium which occurs during the last trimester; evidence of increased neuro-muscular excitability was found by Klaften and others in 85 per cent. of normal pregnancies. Experimentally partial parathyroidectomy often causes tetany, which is curable by the administration of parathyroid extract. There is evidence from several sources that the daughters of women prone to tetany in gestation may themselves suffer similarly in their own pregnancies, and also that the infants of those having gestation tetany are liable to severe attacks soon after birth. Tetany does not appear to lead to abortion, and of the deaths which it has caused those in the puerperium far outnumber those during gestation. Treatment consists in the exhibition of calcium and parathyroid, together with a protective shortening of labour.

Pathology

147



Thermolability of the Tubercle Bacillus

H. J. CORPER and M. L. COHN (*Amer. Rev. Tub.*, May, 1937, p. 663) record the results of a careful study made to determine the heat resistance of the tubercle bacillus. The human type of bacillus was selected, and both virulent and avirulent strains were used. Very finely divided suspensions in a buffered solution—a modified Long's medium at *pH* 7.0—were prepared from cultures about a month old. A special apparatus was devised to ensure the accuracy of the temperature to which the suspension was heated. Immediately after the exposure the organisms were inoculated on to a suitable culture medium. The results showed that a suspension containing 1 mgm. of bacilli per c.cm. yielded negative subcultures after exposure to a temperature of 55° C. for fifteen to thirty minutes, and to a temperature of 60° C. for less than five minutes. Virulent and avirulent strains behaved alike. In other experiments it was found that the bacilli grew well at 42° C. This temperature is higher than that which can be tolerated for any length of time by the human body. Treatment of tuberculosis by hyperpyrexia therefore holds out little promise of success. A few experiments made in rabbits confirmed this conclusion.

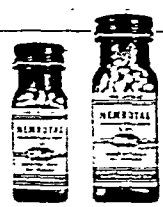
148

Pathogenesis of Circulatory Insufficiency

W. ORLOWSKI (*Arch. Mal. Cœur*, May, 1937, p. 283) has made numerous experiments in healthy persons and in those suffering from heart failure, and has found that there is a change: (1) in the capacity of the blood to take up oxygen, (2) in the utilization of oxygen by the tissues, (3) in the dissociation of haemoglobin, (4) in the hydrocarbon, basal, and mineral metabolism, (5) in the acid-base equilibrium, and (6) in the quantity of circulating blood and in the volume of the blood flowing to the heart in one minute. These changes are less marked when the circulation is normal and the myocardium still strong. They may occur during the disappearance of symptoms of circulatory insufficiency or else afterwards. If appearing in the course of circulatory compensation they are signs of latent insufficiency. The author is of the opinion that neither the mechanical nor the chemical theory of circulatory insufficiency wholly explains these changes. Examination of the action on metabolism of efficacious cardiovascular drugs shows that in addition to their well-known pharmacological action they have an influence on biochemical processes in the body. Orlowski believes that chronic circulatory insufficiency is a disease of the whole organism due to a lack of the functional equilibrium of the tissues and organs resulting in metabolic changes. It expresses itself in a change in the biological properties of the serum, which contain factors influencing the growth of fibroblasts. These accelerate the hydrolysis of the albumins and globulins of the blood serum, and increase their ability to fix alkalis.

ACCOMPLISHES DESIRED EFFECT WITH

ONE-HALF THE DOSAGE



REQUIRED WITH MOST OTHER BARBITURATES

Administered orally, rectally or, in emergencies, intravenously, Nembutal exerts an extremely rapid but brief hypnotic and a pronounced sedative action from a dosage only about one-half that required with most other powerful barbiturates. This small dosage reduces the recovery period also by about one-half and, by lessening the amount of the drug to be eliminated, makes Nembutal, clinically, one of the safest of the barbiturates. ● Safety, rapidity and brevity of action recommend Nembutal for use not only as a pre-anæsthetic sedative in major and minor surgery, but also in the treatment of insomnia, hysteria, sea-sickness, nausea from any cause, eclampsia, delirium tremens, convulsions from strychnine or other poisoning and in obstetrics—with or without morphine and scopolamine. Nembutal has also been used with much success as a supplement to morphine in controlling the pain of early cancer. ● Nembutal is available through pharmacies in a wide variety of forms, the most widely employed of which are the ½-grain and 1½-grain capsules for oral use. The drug is also supplied in the form of 2-grain suppositories. Comprehensive literature and a free trial sample of Nembutal 1½-grain Capsules will be sent upon request. The coupon below is for your convenience.

Mild Constipation shown to yield to laxative effect of HOVIS

Many of the mild forms of constipation so prevalent to-day are attributed to the consumption of foods deficient in Vitamin 'B.' In comparing the effects of various kinds of bread it is seen that HOVIS germ bread is superior to either white bread or wholemeal in supplying this deficiency.

Whilst white bread contains practically no Vitamin 'B,' HOVIS, with its added proportion of 25% wheat-germ, supplies an abundance of this essential food-element. Unlike wholemeal bread, HOVIS contains only a minute percentage of bran and indigestible cellulose. In other words its incorporation in the normal diet ensures not only a higher standard of nutrition but easier assimilation and regular evacuation of the intestinal contents.

VITAMIN 'B' CONTENT ACTS AS AID TO REGULARITY

TRUST *of* BANK & INSURANCE SHARES offers a most convenient method of securing an investment spread over the stocks and shares of 52 leading British banks and insurance companies. *The holder of Bank-Insurance Units is free from all personal liability in respect of uncalled capital.*

Full particulars may be obtained and Units may be bought or sold through any Stockbroker or Bank. The estimated yield at current prices and based on cash dividends is from $3\frac{3}{4}$% to 4%. Price of Bank-Insurance Units, 10th August, 20s. 6d.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBRIDGE, SUFFOLK**

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. (*Toll Call from London.*)

Proprietors. The Norwood Sanatorium, Limited

RUTHIN CASTLE, NORTH WALES

The fees are from 15 guineas a week. They include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary *x*-ray examinations, and electrocardiograph readings; all treatment that may be prescribed such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing; medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary *x*-ray examination, or for *x*-ray therapy.

All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*—Castle, Ruthin. *Telephone*—Ruthin 66

The above House, which was established in 1826, is an Institution for the care and treatment of persons suffering from mental diseases and nervous disorders. Certified voluntary and temporary patients are received. Separate houses for treatment and accommodation of special cases adjoin the Institution. There is a seaside branch, Kearsney Court, near Dover, to which patients may be sent for treatment or on holiday. Motor and carriage exercise is provided as required. Patients can avail themselves of a course of physical drill. Tennis courts. Entertainments, dances, and indoor amusements held throughout the year. Terms from £3 3s. per week. Illustrated prospectus and further particulars can be obtained from the Medical Superintendent.

CHEADLE ROYAL HOSPITAL

CHEADLE, CHESHIRE

This REGISTERED HOSPITAL, with a SEASIDE BRANCH at Colwyn Bay, N. Wales, is for the treatment and care of those of the Upper and Middle Classes suffering from MENTAL and NERVOUS DISEASES. TRUSTEES of the Manchester Royal Infirmary.

The Hospital is governed by a Committee appointed by the Extensive grounds. Hard and grass tennis courts, cricket and croquet grounds, and a court

In addition to the Main Building there are separate villas. Golf may be had within easy distance. Occupational therapy.

for badminton. There are also wireless installations

VOLUNTARY, TEMPORARY, AND CERTIFIED PATIENTS received.

The Hospital is nine miles from Manchester, 50 minutes by rail from Liverpool, and 3½ hours from London.

For terms and further particulars apply to the Medical Superintendent, who may be seen in MANCHESTER by APPOINTMENT.

Telephone: GATLEY 2231 (3 lines).

CHISWICK HOUSE, PINNER, MIDDLESEX.

Telephone: PINNER 234.

A Private Hospital for the Treatment and care of Mental and Nervous Illnesses in both Sexes.

A modern country house, 12 miles from Marble Arch, in beautiful secluded grounds. Fees from 10 guineas per week, inclusive. Cases under Certificate, Voluntary, and Temporary patients received for treatment.

Douglas Macaulay, M.D., D.P.M.

BAILBROOK HOUSE BATH.

For sufferers from Nervous and Mental Disorders with or without certificates. The house is gloriously situated in wooded grounds of 20 acres with magnificent views of the City and the Avon Valley. (See *Medical Directory*, page 2322.)

For terms apply, A. GUIRDHAM, M.A., D.M., B.Ch., D.P.M., Resident Physician.
Telephone: Batheaston 8189.

STRETTON HOUSE, Church Stretton, Shropshire.

A PRIVATE HOME for the treatment of Gentlemen suffering from Mental and Nervous Illness, including the allied disorders of Alcoholism and the Drug Habit. All types of early Mental and Nervous cases are received without certificates as Voluntary Patients under the provisions of the Mental Treatment Act, 1930. See *Medical Directory*, p. 2328.—Apply to the Medical Superintendent, Bracing Hill country. Phone: 10 PO Church Stretton.

THE GROVE HOUSE, CHURCH STRETTON, SHROPSHIRE.

A private Home for the care of and treatment of a limited number of Ladies mentally afflicted. Voluntary and Temporary Patients received under the new Mental Treatment Act, 1930. Medical Superintendent, Dr. MCCLINTOCK.

TYKEFORD ABBEY, NEWPORT PAGNELL, BUCKS.

FUNCTIONAL NERVOUS DISORDERS
MEDICAL AND CONVALESCENT CASES

The Home is a Mansion of Historical interest, standing in 15 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray and Ultra-Violet Light, Diathermy and Foam Baths. Billiards, Tennis, etc.

Apply, Dr. D. E. M. DOUGLAS-MORRIS.
Telephone: Newport Pagnell 121.

Upper Woburn Place, near B.M.A. Headquarters. Accommodates 235 Visitors. Modern Comforts. Excellent table. A.A. and R.A.C. recommended. Room, Bath, and Breakfast from 8/6.

THE MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.
Telephone: RODney 2101

A CLINIC instituted by the London County Council for treatment of Nervous and Curable Mental Disorder. Voluntary patients *only* received.

New Out-patients.—MEN: Mondays and Thursdays, 2 p.m. WOMEN: Tuesdays and Fridays, 2 p.m. CHILDREN: Mondays and Fridays, 10 a.m. In-patients: (a) 235 beds (both sexes) in wards or separate rooms, including 35 beds in a ward of King's College Hospital, which is in use as a temporary annexe of the Maudsley Hospital; (b) a special ward (including some private rooms) for those patients of each sex who are paying the full cost and are otherwise suitable. Terms: £5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.

Terms include (with rare exceptions) all forms of treatment, for which there are exceptional facilities as there is a staff of Consultant Specialists, and the Central Laboratory of London County Mental Hospitals is attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., F.R.C.P., F.R.C.S., Medical Superintendent.

BARNWOOD HOUSE

GLOUCESTER

A REGISTERED HOSPITAL for the CARE and TREATMENT OF LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L.M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 300 acres. Voluntary Patients of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Patients is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the Main Hospital.

For particulars as to terms, etc., apply to—
G. W. T. H. FLEMING, M.R.C.S., L.R.C.P., D.P.M., *Medical Supt.*
Telephone: No. 6207 Barnwood.

HEIGHAM HALL, NORWICH

A PRIVATE MENTAL HOME, situated in 11 acres of well-wooded grounds. For Ladies and Gentlemen suffering from Nervous or Mental Illness. Voluntary Patients, Temporary Patients, and Patients under Certificate are admitted for treatment. Fees: from 4 guineas a week upwards, according to requirements. A few vacancies exist for Ladies and Gentlemen at reduced fees on the recommendation of the Patient's own Physician. Apply to Dr. J. A. SMALL. Telephone: 80 Norwich. Telegrams: Small 80 Norwich.

THE GRANGE,

near ROTHERHAM.

A HOUSE licensed for the reception of a limited number of Ladies suffering from Nervous and Mental disorders. Both certified and voluntary patients received. Approved for temporary Patients. This is a large country house, with beautiful grounds and park, five miles from Sheffield. Tel. No. 40030 Ecclesfield. Res. Phys.: GILBERT E. MOULD, L.R.C.P., M.R.C.S. Station: Grange Lane L. & N.E. Rly.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment

NORTHUMBERLAND HOUSE,

GREEN LANES, FINSBURY PARK, N.4.

A PRIVATE HOSPITAL for the treatment of mental and nervous illnesses. Conveniently situated and easy of access from all parts. Six acres of ground, highly situated, facing Finsbury Park. Voluntary and Temporary Patients received without certification. Occupational Therapy, Psychotherapy, and other modern forms of treatment.

Telephone: STAMFORD HILL 2688. Telegrams: "SUBSIDIARY, LONDON."
Convalescent Home, KEARSNEY COURT, DOVER. For further particulars, apply to the Medical Sup.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

J. S. MUIRHEAD,
July, 1937. *Secretary of University Court.*

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL

THE WINTER SESSION will Open on Friday, October 1st.

The LONDON HOSPITAL serves the East End of London, and with eight hundred and fifty beds is the largest voluntary Hospital in England. Its Out-patient Department, which deals with a hundred thousand new patients per annum, is extensively used for teaching.

The size of the Hospital necessitates a large number of resident medical officers. Every year seventy resident house physicians and house surgeons and eighty salaried non-resident clinical assistants are appointed from among recently qualified students. The opportunities which these appointments offer for obtaining clinical experience is invaluable.

The MEDICAL COLLEGE is attached to the Hospital and is staffed by Professors of Anatomy, Physiology, Bacteriology, Chemical Pathology, Medicine, Anatomy and Medicine of the University of London.

SPECIAL COURSES in Anatomy and Physiology for the Primary F.R.C.S. and Advanced Courses in Surgery for the Final F.R.C.S. Examinations, and in Medicine for the M.D. and M.R.C.P. Examinations, are held twice a year.

ENTRANCE SCHOLARSHIPS AND PRIZES of the total value of £950 are awarded annually. Research Funds to the value of £1,000 per annum are at the disposal of the Medical Committee, assistance being given to students and graduates engaged in medical research.

The MEDICAL COLLEGE contains a modern Museum of Pathology and a Library provided with all the current medical periodicals in charge of a full-time librarian. There is also an Athenaeum Club and Dining Hall, a Gymnasium, a Fives Court and two Squash Courts in the Students' Hostel. The Athletic Ground of 13 acres at Hale End is within easy distance of the Hospital.

The HOSPITAL is only 20 minutes from Charing Cross and Baker Street Stations. For those who wish to live in immediate proximity to the Hospital there is accommodation for sixty students in the Students' Hostel.

Further details may be obtained from the Dean, Dr. A. F. CLARK-KENNEDY, M.D., F.R.C.P., Physician to the Hospital and Fellow of Corpus Christi College, Cambridge, who is always pleased to meet students wishing to see the Hospital and College, and to whom application for admission should be made, Turner Street, London, E.1.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION

INTENSIVE SURGICAL COURSE for GRADUATES contemplating HIGHER DEGREES.

The Course will consist of daily Clinical Demonstrations in the Royal, Western, and Victoria Infirmaries, and systematic lectures on Surgery, Surgical Anatomy, Surgical Pathology, and Operative Surgery. It will run for six weeks, commencing last week of October. Detailed syllabus in September.

Further particulars from the Secretary, Post-Graduate Medical Association, The University, Glasgow.

UNIVERSITY OF LONDON

EXTERNAL EXAMINERSHIPS, 1938.

The Senate announce the following vacant External Examinerships for the year 1938. There is one vacancy in each subject.

Final and Higher Examinations for Medical Degrees.

FORENSIC MEDICINE.
HYGIENE.

Application Form (or Forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, A. Clow Ford, M.B.E., B.A., with any attestation of their qualifications they may think desirable, on or before Wednesday, September 15th, 1937. (Envelopes should be marked "Examinerships.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted, one copy only of each is required. In no case should original testimonials be submitted.

HERBERT L. EASON,
Principal.

University of London,
W.C. 1.

BOROUGH OF STRETFORD

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified medical practitioners for the whole-time appointment of Assistant Medical Officer of Health and Assistant School Medical Officer at a commencing salary of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum.

Applicants must have had at least three years' experience in the practice of their profession subsequent to obtaining a registrable qualification, and must also hold the Diploma in Public Health.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

The terms and conditions of appointment, together with form of application, may be obtained from the Medical Officer of Health, Town Hall, Stretford, and all applications must be received by the undersigned not later than August 21st, 1937.

C. TREWAVAS,
Town Clerk.

Town Hall,
Talbot Road, Stretford.

BRITISH EMPIRE CANCER CAMPAIGN.

A STUDENTSHIP is offered to a young graduate in medicine of science desiring experience in the experimental study of malignant growths from the biological and particularly from the virus aspect, with a view to undertaking independent investigation later in this field.

Consideration will be given to any special interest or experience submitted by candidates—e.g., previous training in histopathological or immunological methods, or in pathological and physiological chemistry.

The selected candidate will be attached to the Lister Institute of Preventive Medicine. The Studentship will be tenable for three years, but subject to annual renewal on report of satisfactory progress. The value of the Studentship will be £300 for the first, £350 for the second, and £400 for the third year if the selected candidate is medically qualified, and £250, £300 and £350 if the candidate holds a degree in science.

Applications, with full particulars of academic and postgraduate career, together with names of two referees familiar with the candidate's career and work, to be sent to the General Secretary, British Empire Cancer Campaign, 11, Grosvenor Crescent, London, S.W.1, before September 7th.

LIVERPOOL COUNTY BOROUGH LOCAL EDUCATION AUTHORITY

ASSISTANT SCHOOL MEDICAL OFFICERS.

Applications are invited for Two Assistant School Medical Officers in the Department of the Medical Officer to the Local Education Authority, at a salary in each case of £500 per annum, rising by annual increments of £25 to £700 per annum.

(Where a successful candidate holds a similar appointment under another Local Education Authority, and receives a salary in excess of the advertised minimum, a commencing salary of not less than the salary which the candidate is receiving under his (or her) existing appointment (not exceeding the maximum under the Liverpool Scale) may be paid.)

Candidates must be registered medical practitioners, and must have had at least three years' experience. It is desirable that they should have had some special experience in school hygiene and in diseases of children.

The officers appointed will be required to reside within the City, and devote whole-time service to the Local Education Authority under the direction of the Medical Officer to the Local Education Authority, and will not be allowed to undertake any private practice.

The appointments will be subject to the Local Government and Other Officers' Superannuation Act, 1922, and the Standing Orders of the City Council.

Form of application, which may be obtained by forwarding a stamped addressed foolscap envelope, should be returned, together with copies of three recent testimonials, to the undersigned not later than August 24th, 1937, and endorsed "Assistant School Medical Officer."

The canvassing of members of the Education Committee or of the City Council is strictly prohibited, and will be considered a disqualification.

W. H. BAINES,
Municipal Buildings, Town Clerk and Clerk to the
Liverpool, 2. Local Education Authority.
August 13th, 1937.

LIVERPOOL COUNTY BOROUGH LOCAL EDUCATION AUTHORITY.

ASSISTANT SCHOOL DENTAL OFFICER.

Applications are invited for an Assistant School Dental Officer in the Department of the Medical Officer to the Local Education Authority, at a commencing salary of £500 per annum, rising by annual increments of £25 to £600 per annum.

(Where the successful candidate holds a similar appointment under another Local Education Authority, and receives a salary in excess of the advertised minimum, a commencing salary of not less than the salary which the candidate is receiving under his (or her) existing appointment (not exceeding the maximum under the Liverpool Scale) may be paid.)

Candidates must be registered Dental Practitioners, and previous experience of school dental work will be a recommendation.

The officer appointed will be required to reside within the City and devote whole-time service to the Local Education Authority under the direction of the Medical Officer to the Local Education Authority, and will not be allowed to undertake any private practice.

The appointment will be subject to the Local Government and Other Officers' Superannuation Act, 1922, and the Standing Orders of the City Council.

Form of application, which may be obtained by forwarding a stamped addressed foolscap envelope, should be returned, together with copies of three recent testimonials, to the undersigned not later than August 28th, 1937, and endorsed "Assistant School Dental Officer."

The canvassing of members of the Education Committee or the City Council is strictly prohibited, and will be considered a disqualification.

W. H. BAINES,
Municipal Buildings, Town Clerk, and Clerk to the
Liverpool, 2. Local Education Authority.
August 13th, 1937.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medieal Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

ROWLEY REGIS BOROUGH COUNCIL.

DEPUTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Female).

The Council of the Borough of Rowley Regis invite applications for the above whole-time appointment from duly qualified Registered Medical Practitioners holding a Diploma of Public Health and not over 40 years of age. The officer appointed must have had experience in Maternity and Child Welfare, Pre-natal and School Medical Work, and must possess the necessary qualifications to act as Medical Supervisor of Midwives. The salary will be £600, and will rise, subject to satisfactory service, by annual increments of £25 to £700 per annum, and travelling expenses, in accordance with the Council's scale, will be allowed.

Candidates must apply on the prescribed form, to be obtained from Dr. Frank Asker, Medical Officer of Health, Haden Hill Park Offices, Old Hill, Staffs, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than Monday, August 23rd, 1937.

Council Offices, Old Hill, Staffs. C. BUCKLEY, Town Clerk.

STAFFORDSHIRE COUNTY COUNCIL.
WORDSLEY PUBLIC ASSISTANCE INSTITUTION.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered medical practitioners (male) for the post of Assistant Medical Officer (Resident) at Wordsley Public Assistance Institution, near Stourbridge Salary £300 per annum, with board, residence and laundry Candidates should be unmarried.

The appointment will be, in the first instance, for a period of six months, but the successful candidate will be eligible for reappointment for a further period of six months.

The Institution is in process of conversion into a Hospital, and facilities will be available for gaining experience in medicine, surgery, midwifery, and diseases of children.

Further details may be obtained on application to the County Medical Officer of Health.

Applications, stating age, qualifications and experience, with copies of testimonials, should be sent to the undersigned not later than Thursday, August 19th, 1937.

County Buildings, Stafford. H. L. UNDERWOOD, Clerk of the County Council.
July 30th, 1937.

CITY OF BIRMINGHAM.

SELLY OAK HOSPITAL (520 Beds).

RESIDENT GYNAECOLOGIST AND OBSTETRICIAN (male).

Applications are invited for the above whole-time appointment from fully qualified registered medical practitioners who have had good experience in Gynaecology and Obstetrics, and who are Fellows of the Royal College of Surgeons (England).

Furnished quarters, rations, laundry and attendance will be provided, or alternatively a cash allowance will be paid if the officer appointed should be non-resident.

Salary will be £700, rising by annual increments of £50, to a maximum of £1,000 per annum, together with the emoluments stated above.

The appointment will be dependent on the candidate passing a medical examination and be subject to the Birmingham Corporation's Superannuation Scheme; and the Birmingham Municipal Officers' Widows' and Orphans' Pensions Scheme (if applicable). The appointment will be terminable by one month's notice on either side. The officer appointed will be required to refund to the Council all fees and allowances received in connexion with his duties.

Further particulars of the appointment may be obtained from the Medical Superintendent of the Hospital.

Applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, and endorsed "Gynaecologist and Obstetrician," should be sent to the Medical Superintendent not later than August 21st, 1937.

BOVRIL MEDICAL AGENCY, LTD.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, LESQUARE, LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Chairman and Managing Director, Dr. J. FIELD HALL.

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges. No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. SURREY.—Pleasant district in outskirts of London.—A SIXTH SHARE is offered in an old-established practice producing for the past 12 months about £4,500. Panel of approximately 1,800 patients. Good house available on rental. Ingoing man should be over 30, married and preferably a Protestant.
2. BORDERS OF HAMPSHIRE AND BERKSHIRE.—Old-established country PRACTICE. Receipts for past 12 months about £1,200 including £372 from panel of about 660 patients. Suitable house available on rental at £70 p.a. approximately inclusive. Premium £1,550.
3. DEVON COUNTRY.—Old-established PRACTICE producing about £600 p.a. including about £310 from panel of 428 patients. *Freehold* house for disposal containing 2 reception rooms, lounge hall, 6 bedrooms, waiting room, consulting room, etc., 1½ acres of garden, garage for 2 cars and stabling. Freehold £2,600. Premium £1,200.
4. CENTRAL LONDON.—Owing to illness, old-established PRACTICE producing about £2,300 p.a. Panel of over 3,100 patients. Suitable accommodation available on rental. There is an appointment producing £160 p.a. which is not included in the above receipts but which is believed to be transferable.
5. LANCS.—Suburb of large town. PRACTICE producing about £800 p.a. with panel of 467 patients. Suitable house on rental at £90 p.a. inclusive. Stated to be scope for increase. Premium £1,100.
6. DEATH VACANCY.—BAYSWATER, W. 2.—Good class PRACTICE producing about £840 p.a. but has been considerably more. Receipts have decreased owing to ill health. Fees 10,6—no panel. House available on rental or practice could be taken over separately. Premium 1 year's purchase.
7. LONDON, S.E. 11.—Old-established working class PRACTICE producing approximately £500 p.a. Panel of about 500 patients. Can be worked as lock-up. Premium 1 year's purchase or any reasonable offer accepted.
8. YORKS.—LARGE TOWN.—Well-established better working-class PRACTICE. [illegible] el of 1,150 patients approx[imately]. 7/6. Free[hold] house for [illegible] coms, surgery, waiting r[oom]
9. SURREY.—Pl[easant] [illegible] 12 months about £1,280 with a Panel of 800 patients. Fees 3/6 upwards, with visits from 5/- upwards. Midwifery 3 to 10 gns., about 15 cases per annum. Vendor has to give up owing to ill-health. Premium £2,000.
10. EASTERN COUNTY AND MARKET TOWN.—HALF-SHARE PARTNERSHIP in Practice established some 100 years, owing to retiral of junior partner. Average cash receipts over £2,400 p.a., of which over £700 comes from Panel and P.A.C. Suitable house available on rental. Ingoing partner should not be more than 30, preferably have a degree and some hospital experience.
11. ASSISTANTSHIP—with a view to a PARTNERSHIP SHARE to produce about £1,100 p.a., in a well-established Practice. Ingoing man must be young, have had considerable hospital experience, and preferably held an Ophthalmic H.S. He should be married or engaged, and a Protestant. Will applicants please give fully details of experience, etc.
12. DEVON, SOUTH COAST.—A well-established good-class entirely private PRACTICE producing for the past 12 months about £1,600. Panel could be had if desired. Fees 2/6, 3/6, 5/- and 7/6, with a few visits up to 21/-. Non-dispensing. Suitable house containing consulting room, 2 reception rooms, 6 bedrooms, for sale. Freehold £1,400. Partnership introduction. Would be suitable for ex-I.M.S. or similar.
13. NORFOLK AND SUFFOLK BORDERS.—A SHARE to produce about £1,100 p.a., is offered in an old-established Practice with considerable scope for increase. Receipts approximately £3,300 with a Panel of some 1,400 patients. Expenses are very low and there is likely to be a choice of houses.
14. DEVELOPING NORTHERN SUBURB.—A 3/8TH SHARE is offered in a well-established and growing Practice. Receipts for 12 months to 1/4/37 amounted to about £5,200, including about £80 from appointments and a Panel of some 5,300 patients. There is a choice of houses available.
15. LANCS.—SUBURB OF LARGE TOWN.—PRACTICE established for 10 years—gross cash receipts for year ended 31/3/37 amounted to about £800, with an increasing Panel of some 470 patients. Fees 2/6 and 3/6, with visits 3/6 and 5/-. Suitable house with good accommodation and separate surgery available on lease at £60 p.a. Premium £1,100, plus good debts, drugs and surgery equipment at valuation. Vendor giving up owing to ill-health.
16. WEST COAST.—Well-established PRACTICE producing about £1,900 p.a., including Panel of 1,450 patients which gives £820 p.a. and one or two small appointments. Visits 3/6 to 12/6. Consultations 3/6, medicine extra. There is a Cottage Hospital, purchaser would get on the staff. There is stated to be scope for surgery. Suitable house on rental at £50 p.a., with rates of £26 p.a. Accommodation is ample, and consists of waiting and consulting room, dispensary with separate entrance, 2 reception, 7 bedrooms and billiard room, half-acre of garden and garage for 2 cars. Premium 1½ years' purchase.
17. [illegible] PRACTICE for disposal. Gross income 350 patients. There is also a possibility [illegible]ospital appointment worth about £120 p.a. House can be rented on lease or purchased.
18. LONDON, E.2.—Lock-up PRACTICE established 80 years for disposal. Income about £800-£900 p.a., with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available consisting of consulting room, dispensary, waiting room, the remainder being sub-let for £250 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £150 fittings, fixtures, drugs, etc.
19. CENTRAL LONDON.—Long-established PRACTICE for disposal owing to ill-health. Income about £2,300 p.a. Panel of over 3,100 patients. There is also an appointment producing £160 p.a., which is not included in above [illegible] mmodation available.
20. [illegible] 30, producing about [illegible] Suitable accommodation available.
21. BAYSWATER.—PRACTICE established some 65 years for disposal. Gross receipts about £1,440 p.a., with 1,000 Panel patients. Suitable house on lease at £130 p.a. Premium 2 years' purchase.
22. ESSEX COAST TOWN.—A ONE-THIRD SHARE is offered to a physician in an old-established Practice producing about £7,200 p.a. Panel produces about £900 p.a. Consultations 3/6 to 7,6. Visits 5/- to 21/-. There will probably be a choice of houses. Ingoing partner should be aged 35 or over and must have a good hospital experience. He should hold the M.D. or M.R.C.P.
23. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be 28-40, preferably hold a degree and must have their English Fellowship. Premium 2 years' purchase.
24. NORTH LONDON.—PRACTICE producing £753 p.a., including £322 from Panel and £135 from one appointment. Fees 2/6 to 3/6. Visits 3/6 to 5/-. Suitable accommodation available, 2 consulting rooms, waiting room and dispensary with separate entrance—2 reception rooms, 7 bedrooms. Nett outgoings approximately £107 p.a. Premium £1,250.
25. LONDON, S.W.—Old-established PRACTICE producing £1,500 p.a., with panel of 1,266 patients for disposal. Appointment and small club bring in about £85 p.a. House available contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. Premium £3,000.
26. NORTH-WEST COAST.—SEASIDE TOWN.—CONSULTING PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320. Minimum fee 2 gns. Suitable rooms available at inclusive rental of £44 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1½ years' purchase on actual receipts for first year.
27. HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc., Professional accommodation. Good garden and garage. Rent £55 p.a. Prem. £1,250.
28. LONDON, SOUTH-EAST.—Middle-class PRACTICE held by vendor nearly 30 years, averaging over £700 p.a. Panel of 576 and one appointment worth £25 p.a. Roomy house with good garden and garage. Leasehold for sale.
29. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¼ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house m[ay]
30. LONDO[N] [illegible] produci[ng] [illegible] a young man who will undertake panel and midwifery. Fees 3/6 to 10/6. Small compact house on rental. Premium £1,500.
31. SOUTH-COAST SEAPORT.—Long-established PRACTICE for disposal owing to Vendor's retirement. He has held it for the past 39 years. Income last year approximately £573 with a Panel of about 460 patients. Vendor previously held a public appointment producing £450 p.a., which he relinquished owing to age limit. It is considered that anyone devoting whole time to the Practice would increase the receipts. Suitable accommodation
32. [illegible] PRACTICE in pleasant agricultural [illegible] er £1,300 p.a. Fees 3/6 to 21/-. Nice house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, garage. Price for freehold £1,300. Sport of all kinds and schools within reach.
33. EAST ANGLIA.—WITHIN REACH OF TWO GOOD TOWNS.—Old-established, unopposed country PRACTICE averaging over £1,000 p.a., including Panel producing over £450 a year. Low expenses. Detached house in own grounds, containing 2 sitting rooms, 5 bedrooms, etc. Rent £70 a year. Premium £1,750.
34. LONDON.—NORTH-WEST.—Recently established and steadily developing PRACTICE producing for last 12 months approximately £1,000, and increasing at the rate of about £200 p.a. Suitable house can be rented or flat obtainable. Premium 2 years' purchase.
35. NORTH-EAST COAST.—Old-established PRACTICE producing about £900 p.a., but stated to be capable of considerable increase. Choice of houses. Partnership introduction given, as vendor retiring.
36. [illegible] DENTIAL TOWN.—Chiefly better [illegible] ducing for last 12 months over £1,600. [illegible]nth £150 p.a. Fees 3/6 to 21/-. Very [illegible], garden and garage. Freehold for sale. Premium 2 years' purchase.
37. CENTRAL LONDON.—PRACTICE is worked as a "Lock-up" and averages about £1,000 p.a. Fees from 2/6. Suitable accommodation can be obtained. Premium 2 years' purchase.
38. SUSSEX.—ATTRACTIVE DISTRICT NEAR SEA.—PARTNERSHIP.—A ONE-FOURTH SHARE is offered (after preliminary assistantship of 6 to 12 months) in old-established Practice having good scope. Gross cash receipts for last 12 months approximately £3,275. Panel of about 1,300. Appointments worth over £300. Choice of houses on rental for ingoing partner. Premium 2 years' purchase.
39. SUSSEX COAST TOWN.—PRACTICE established 45 years for disposal owing to retirement of Vendor. Present receipts about £600. There is stated to be scope for increase as receipts have fallen owing to Vendor's illness. Panel about 650. Large house can be rented at £150, or purchaser could probably choose own residence.
40. LONDON.—SOUTH-EAST.—Old-established PRACTICE producing about £1,830 p.a., including select panel of 500. Fees from 3/6. Suitable house available with 2 recep., 5 bedrooms, etc. Freehold for sale. Prem. 2 years' pur.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Valentine's Meat-Juice

In Typhoid Fever, Diarrhoea and Cholera Infantum, when it is Essential to Sustain the patient without irritating the Digestive Organs, the Ease of Assimilation and Power of Valentine's Meat-Juice to Restore and Strengthen has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

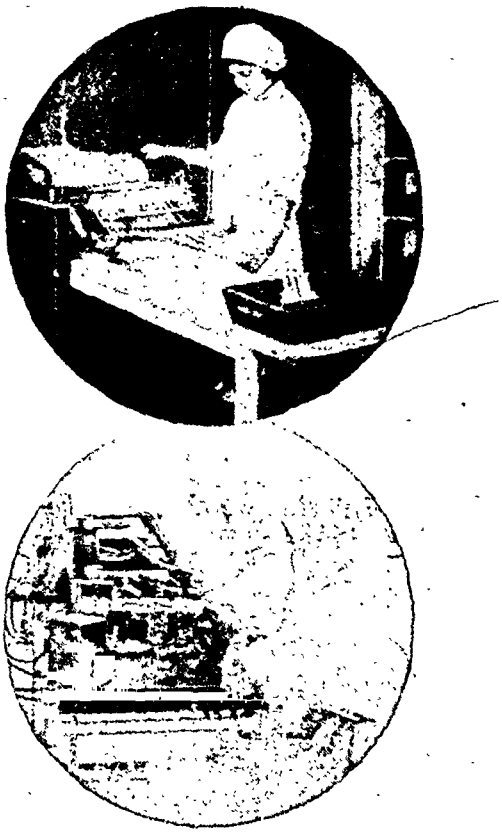
For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
RICHMOND, VIRGINIA, U.S.A.

WB 302

Heat Sterilized without loss of flexibility

Surgical Catgut is manufactured from the submucous cellular coat of the sheep's intestine.



This material is converted into gelatin by the action of heat in the presence of moisture.

Heat sterilization is carried out therefore, after complete dehydration of the catgut. After sterilization, the tubes of catgut are filled with a 96% alcoholic solution, the 4% aqueous content imparting flexibility to the suture.

This variety of catgut, as taken from the tube, has the correct degree of flexibility and tensile strength. The suture requires no conditioning before use.

The entire product manufactured in England.

Descriptive booklet will be sent on application.

TOP—Removal of the mucous coat by mechanical means, before decomposition commences.
BOTTOM—Hermetically sealing glass tubes containing sterile catgut.

ELECTRIC FIRES
for the best kind of warmth

Does every medical practitioner yet realise what an ideal heating agent the modern electric fire is, both for general domestic use and for the sick room? For instance, electric fires are the only type that give perfect balance between radiation and convection. The convected heat of ordinary fires cannot be utilised because it is smoke or fume laden. On the other hand, hot pipes give convected heat only. But the electric fire gives cheerful radiation plus convected heat which is absolutely free from contamination—just pure air—warmed, and it is convection that gives warm comfort to a room—radiation alone is too localised, so that electric fires give much the best kind of warmth

Electric fires create no dirt and no fumes. They require no laying or tending. Are always ready for use day or night. In short, they are more nearly the ideal heating agent for convenience and hygiene than any heating system that the world has yet seen

For further information apply to the British Electrical Development Association, 2 Savoy Hill, London, W.C.2, or consult your local Electricity Authority

INCREASED RATES OF BONUS
ARE NOW ANNOUNCED BY THE
MEDICAL SICKNESS SOCIETY

All members holding With Profit Sickness and Accident Policies or Life Assurance Policies share in the prosperity of this Mutual concern which deals exclusively with the Medical and Dental Professions.

Non-members should apply for details of the Permanent Sickness Contract which gives benefits up to age 65 and a substantial cash bonus at that age. Even with these advantages the premium is the cheapest obtainable.

HOW
CADBURY'S MILK CHOCOLATE
MEETS A REAL NEED
FOR THE ORDINARY MAN AND WOMAN

Too long a gap between meals—and recent research has shown that the big conventional meals *are* too far apart—reduces efficiency and introduces an element of strain into everyday life.

Some small but nourishing between-meal snack is markedly beneficial *in every normal case—milk is an example of a food that perfectly* fulfils the necessary conditions. Unfortunately, however, the conditions of their work prevent many men and women to-day from taking any save the most compact and portable forms of nourishment in these long between-meal gaps. It is here that Cadbury's Milk Chocolate, at once handy, nourishing and energising, proves of the greatest value. Where the consumption of liquid milk would be impracticable, Cadbury's Milk Chocolate supplies all its goodness in concentrated form.

A vitamin assay of samples of Cadbury's Milk Chocolate taken from current production and tested by the highest independent authority indicates that this chocolate contains 6 International Units of Vitamin A per gram as compared with a stated potency for milk of 3 International Units per gram.

It will thus be seen that the process by which milk is converted for use in Cadbury's Milk Chocolate results in the concentration of its goodness without the modification or loss of those qualities which make milk so valuable a food.

1½ glasses of full-cream milk contained in every ½ lb. block

AN INCENTIVE TO GARGLING

When the routine of gargling night and morning is prescribed, it is more likely to be carried out regularly when the preparation used is a pleasant one. 'Dettolin' mouthwash and gargle, which contains (amongst other things) the active germicidal principle of 'Dettol,' is a highly efficient bactericide. Yet in both taste and smell it is most agreeable to use. It will be found of great assistance in treating sore and septic throats and inflamed conditions of the mouth. 'DETTOLIN' *is obtainable through Chemists and Medical Suppliers, Price* 1/6. *Samples and full information on request.*

Disorders of Digestion and Nutrition in Infants and Young Children

LUIZYM has been of inestimable value to us in suppressing the undoubted danger, particularly rife in summer, of digestive disorders due to an insufficiency of active enzymes. Luizym assists these enzymes and ferments in the disintegration of vegetable foods and also prevents excessive development of intestinal gases.
Waber: Cernauti Medical 1936, *No.* 7, *p.* 495.

With the aid of LUIZYM infants are able to take highly nutritious vegetable food without any fear of the dangerous disorders of digestion or nutrition that occur, particularly in the hot months, when such change of diet is made.

Samples and Literature sent on application.

MEDICAL LABORATORIES LTD.
40, PALL MALL, LONDON, S.W.1
Telephone: WHitehall 2486.

Method of use: One LUIZYM tablet to be given per 100 grm. of vegetable food. The powdered tablet should be stirred into the sieved vegetables

In bottles of 20 and 50 tablets.

Ergoapiol-(Smith)

A Menstrual Regulator . . .

When the periods are irregular, due to constitutional causes, ERGOAPIOL (Smith) is a reliable prescription. Containing apiol (M.H.S. special) together with ergot, aloin and oil of savin of the highest quality, this preparation effectively stimulates uterine tone and controls menstrual and postpartum bleeding.

In cases of *Amenorrhœa*, *Dysmenorrhœa*, *Menorrhagia* and *Metrorrhagia*, Ergoapiol serves as a good uterine tonic and hemostatic. Valuable in obstetrics after delivery of the child and for the menstrual irregularity of the *Menopause*.

Prescribe 1 to 2 capsules 3 or 4 times daily. Supplied only in packages of 20 capsules. Literature on request.

As a safeguard against imposition the letters MHS are embossed on the inner surface of each capsule, visible only when the capsule is cut in half at seam as shown.

"The Fuels of Muscular Activity"

Under this title, Professor L. Brouha—one of the most distinguished savants of Belgium, with an already world-wide reputation for his investigation of the hormones—once more stresses the importance of carbohydrates as the essential fuel for muscular activity.

His conclusions are thus summarised in popular language by Dr. Fafner of Brussels:

"You wish to gain strength which will enable you to work without abnormal fatigue? Utilise carbohydrates —sugars, starches, that is to say, BREAD, for that is the typical food rich in carbohydrates already in part pre-digested by the process of baking and the action of the yeast."

BREAD FOR ENERGY

C.F.H.328

Whenever liver is indicated give

Hepferol
BRAND

Active Liver Principles with Iron in Palatable Granule form

4 & 8 oz. Boxes

In cases of pernicious anæmia and in all anæmic conditions which do not respond sufficiently to iron therapy alone HEPFEROL is especially indicated. Prepared from a standardised dry extract of liver with added iron. Readily assimilated by the organism. Constancy guaranteed.

When iron is indicated prescribe

IDOZAN
BRAND

5% of Fe Colloidal Iron Solution

8, 40 & 80 oz. Bottles

IDOZAN meets the fundamental requirements of an effective iron therapy. It establishes a strong positive iron balance, it is easily absorbed from the intestinal canal, providing a ready and abundant storing of surplus iron. IDOZAN is non-constipating, non-irritating and does not discolour the teeth.

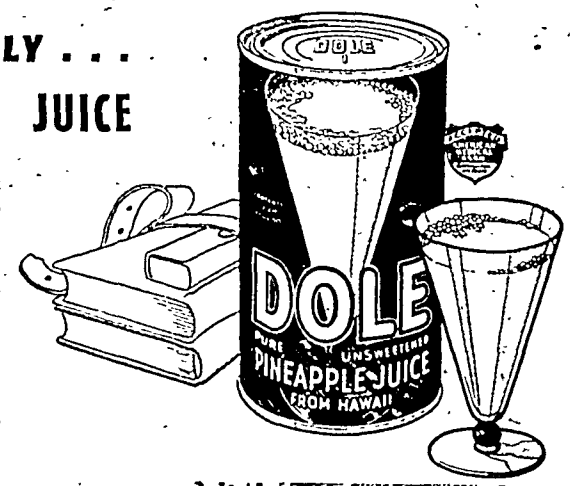
The respective merits of

DETOXICATED and TOXIC VACCINES

The obvious advantage of Detoxicated Vaccines is that large doses can be administered without causing serious reactions. This is of great value in the treatment of cases where any given bacterial disease is already established. In such cases toxic vaccines are apt only to aggravate the symptoms, whereas moderate doses of the appropriate detoxicated vaccine can be given safely without further aggravation of the disease.



We have always upheld the superiority of detoxicated vaccines, but some authorities prefer the toxic varieties because they believe that it is important to obtain more or less marked reactions in order to produce a satisfactory immunity.

The toxic vaccines have the advantage of cheapness. The detoxicated vaccines are more expensive, for the obvious reason that the dosage is nearly one hundred times greater, so that much larger quantities of bacteria are used in their preparation.

We supply both the detoxicated and the toxic varieties of vaccines in order to cater for the two different schools of thought in this matter. A booklet, giving details of our full range of Detoxicated and Ordinary Vaccines, will gladly be supplied on request.

SCHOOL CHILDREN *ESPECIALLY* . . .
ARE FOND OF THIS PURE FRUIT JUICE

GOOD work, as every doctor knows, is very often dependent upon good health. And a well-regulated diet is important for maintaining good health.

Dole Hawaiian Pineapple Juice is the natural juice of sun-ripened, Dole-grown pineapples. It contains no added sugar or preservatives of any kind.

The exclusive Dole Fast-Seal Vacuum-Packing Process retains, to a high degree, those important fresh-fruit constituents found in the ripened pineapple so valuable, not only to growing children, but to adults as well! Also, this tangy, tropical juice is a natural source of vitamins A, B, and C. That's why, with schooltime, when parents are asking about diets and menus for their children, you can recommend with assurance pure, unsweetened Dole Pineapple Juice—the original pineapple juice from Hawaii.

J. K. Husband & Co., Ltd., 10 Eastcheap, London, E.C. 3.

HERE IS A TYPICAL ANALYSIS OF DOLE PINEAPPLE JUICE:

Moisture	85.3%	Crude Fibre	0.02%
Ash	0.4	Titratable acidity as citric acid	0.9
Fat (ether extract)	0.3	Reducing sugars as invert sugar	12.4
Protein (N × 6.25)	0.3	Carbohydrates other than sugars (by difference)	0.38

P.S. We would like you to enjoy a long cool glass of this refreshing juice! Write to us on your letterhead and we will send you a sample tin free.

THE LEI WOMAN—An old Hawaiian custom ever new is [illegible] parting or returning friend[s] [illegible] native flowers. The fragr[ance] [illegible] kake and ginger are used ca[illegible] [illegible]s. It is a picturesque sight on steamer days to see the native women with their skilful hands weaving the fragrant garlands.

MARMITE
(YEAST EXTRACT)

For vitamin B_1 and vitamin B_2 complex

The value of supplementing restricted diets with Marmite, for its high vitamin content, is becoming increasingly appreciated. It is considered particularly beneficial in diabetes and colitis. An authority outlining the dietetic treatment of gastro-duodenal haemorrhage states :—

"Marmite is given at least once a day for the vitamin B complex."
(*Brit. Med. Journ., April 24th*, 1937, *p.* 847)

As a therapeutic agent in disorders associated with deficiency of vitamin B_1 or the B_2 complex, Marmite is prescribed extensively. In a recently published paper, referring to pellagrous conditions, case reports are quoted which illustrate

"the dramatic effect of Marmite on the skin lesions." (*Lancet, May 22nd*, 1937, *p.* 1225)

Marmite is also ordered for its specific haemopoietic properties in the treatment of certain forms of anaemia.

For sample and literature apply to:—

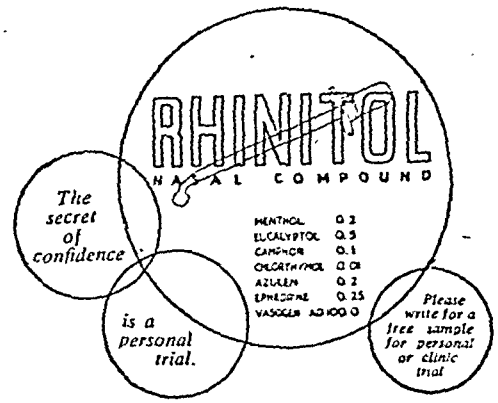
THE MARMITE FOOD EXTRACT CO. LTD., Walsingham House, Seething Lane, London, E.C. 3

In jars: 1-oz. 6d., 2-oz. 10d., 4-oz. 1s. 6d., 8-oz. 2s. 6d., 16-oz. 4s. 6d.

376/1/H Special quotations for Marmite packed for use in hospitals, clinics, welfare centres, etc.

Prescribing with Confidence

The advantages of Rhinitol in the treatment of



COLDS

NASAL CONGESTION and CATARRH

and all other affections of the upper respiratory tract are :—

1. Its very low ephedrine content.
2. Its property of emulsifying with body fluids owing to the vasogen vehicle.
3. Its complete freedom from irritant or toxic effects.
4. Its rapid yet prolonged action.

THYMINIC ACID BASE

URALYSOL

TRADE MARK

FORMULA

Thyminic Acid	0·10
Hexamethylenetetramine Anhydromethylenecitrate	0·50
Hexamethylene Tetramine	2·50
Piperazine Tartrate ..	0·25
Lithium Carbonate ..	1·00
Sodium Benzoate ..	1·00
Effervescent Base ..	ad 100

DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

Uralysol, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

Nestlé's

. . *experienced with Baby Foods*

supply **HOMOGENISED** Fruits and Vegetables

ALL the difficulties associated with the adding of fruits and vegetables to infant diet are overcome by the use of Nestlé's Homogenised Vegetables, Fruits and Soup. Homogenisation breaks down the cell walls of these foods, making them more assimilable than any commercially strained product or home-made soup. Clinical tests showed that infants as young as four months thrived on Homogenised Foods, cases of nutritional anaemia improved, constipation was overcome, and there was no case of colic or other digestive disturbance. Samples of Nestlé's Homogenised Foods, together with an interesting brochure are now available for your own testing purposes, and will be sent at once on receipt of the coupon.

Photo-micrograph of commercially strained prunes.

Nestlé's Homogenised Fruits.

ALASIL

Safe Salicylate Therapy

THE popularity of acetyl-salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non-narcotic analgesics available. Too often, however, its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

"Alasil" provides the beneficial therapeutic effects of pure acetyl-salicylic acid in such a form that it is acceptable even by disordered digestions This tolerability is due to the fact that it combines calcium acetyl-salicylate—the least irritating salicylate compound—with "Alocol," a potent gastric sedative and antacid.

Since "Alasil" is better tolerated than acetyl-salicylic acid its use can be pushed or prolonged to a much greater extent than the latter. "Alasil" is, therefore, an analgesic, antipyretic, and antirheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

A supply for clinical trial, with full descriptive literature, sent free on request.

ANAHÆMIN B.D.H.

In the treatment of pernicious anæmia

Physicians who have adopted anahæmin treatment as a routine in pernicious anæmia testify to the uniformly beneficial effects which invariably result.

The graph reproduced herewith illustrates the response to three injections of anahæmin in a case recently reported (Brit. Med. Journ, May 22, 1937, p.1090).

In commenting upon the result obtained the physicians concerned stated '... until recently we should undoubtedly have transfused this patient before treating her with liver extract, but similar experience with two other severe cases treated with anahæmin has given us sufficient confidence to wait for the expected reticulocyte crisis about the fifth day.'

Adequate treatment of pernicious anemia with . . .

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT

Lederle

ACCORDING TO OUR INTERPRETATION, adequate treatment implies the treatment of other disease symptoms aside from those referable to the blood (number of red cells, hemoglobin, cell volume): the gastro-intestinal tract (glossitis, diarrhea, loss of appetite) and the nervous system (peripheral and central).

"1 CC. CONCENTRATED SOLUTION LIVER EXTRACT *Lederle*" offers many advantages to the physician and the patient:

- Rapid improvement during relapse;
- Maintenance with a relatively small number of injections per month,
- A minimum of inconvenience to the patient with each injection,
- Intensive therapy, still with little inconvenience, for those patients with extensive neurologic involvement

Clinical experience of the last four years has definitely shown that parenteral liver therapy is the most effective and most economical method of treating pernicious anemia.

Lassitude and Nervous Debility

At this time of year, when the heat of the day is enervating, and when one is almost impatiently awaiting the annual vacation after a year of hard work, both health and temper are apt to suffer. Every day normal physiological functions, such as appetite and sleep, get "out-of-gear", and we feel "frayed". It is just at this time that a true tonic food is needed: it is the psychological moment to decide to take Sanatogen every morning and evening.

"*I have found Sanatogen extremely valuable in the type which, for want of a better name, is known as "nervous debility", the significant features being in those cases, poor appetite, insomnia, restlessness, inability to concentrate, uncertain temper, etc., for which no pathological cause can be detected. It is very good in cases recovering from mental strain in which the exciting cause has ceased as an immediate factor, but has left its effect on the nervous and mental systems.*"—M.R.C.S., L.R.C.P.

ANCIENT ROMAN PROPHYLACTIC CHARM AGAINST THE EVIL EYE, WHICH ILLUSTRATES A MAGICO-MEDICAL METHOD OF WARDING OFF A BELIEVED CAUSE OF SICKNESS AND DEATH.—The Evil Eye, which could "fascinate" and slay by lingering death, is here shown being itself attacked on all sides and slain by a ring of enemies. This design is in marble and is thought to have been built into a wall. It is not only, as a whole, a powerful protector, but each element in its composition is in itself a recognised amulet. The scene shows the Evil Eye being frustrated in its activities by animals furiously attacking it, by a figure sitting upon it in an attitude of contempt, and by an armed man who is stabbing it.

DATE: From prehistoric times. The marble, A.D. c. 150

COPYRIGHT

A Specific Antitoxin for the Treatment of Gonorrhœa

THE treatment of gonorrhœa with a specific antitoxin was described in the "British Medical Journal."* Although serum treatment in gonorrhœa is not new, previous work has been confined almost entirely to the use of anti-bacterial sera prepared by immunizing animals with cultures of the living organisms.

Gonococcus Antitoxin is prepared by immunizing horses with injections of a soluble toxin of the gonococcus, using a method similar to that used in the preparation of Meningococcus Antitoxin. Clinical trial of this Gonococcus Antitoxin has proved distinctly encouraging in acute and chronic cases—both complicated and uncomplicated—and has given results far superior to those obtained with other biological products hitherto available.

MODERN TREATMENT AND RESULTS OF TREATMENT OF FRACTURES OF THE NECK OF THE FEMUR*

BY

ERNEST W. HEY GROVES, M.S., F.R.C.S.

Emeritus Professor of Surgery, Bristol University

As it is only two years since I opened a discussion on this subject at the Melbourne meeting of the Association I propose to make this paper a very short one, setting out what seem to me to be the chief advances that have been made and formulating the questions which we ought to-day to be able to answer about methods and results.

The Smith-Petersen Nail

This device has been a wonderful example of the triumph of practice over theory. It was introduced at a time when the whole trend of surgical opinion was set strongly against "plating" of any kind which involves burying large foreign bodies in the tissues. I well remember when Smith-Petersen introduced his device before a joint meeting of the British and American Orthopaedic Associations in 1929, and how shocked many of us felt at the deliberate reversion to the steel-plate method of fixing fractures. And yet now, less than ten years after, it may be fairly said that the Smith-Petersen nail has completely dominated the situation, not only in America and England but also in Germany, France, Belgium, Austria, and Italy. The rapid adoption of this method has been due to the very quick immediate restoration of function which it affords. The patient who we were accustomed to think of as languishing in bed for months is now able to get up within a week. It is no longer necessary to keep him in a large plaster case for weeks or months, and the whole prospect is changed from one of rather gloomy resignation to one of confident optimism. As in the case of all other surgical advances, zeal has outrun discretion, and extravagant claims are made which may lead to disillusionment later.

The great merit of Smith-Petersen's nail is that it affords the maximum of mechanical fixation with the minimum of trauma or destruction of tissue. The three flanges control rotation of the bone fragments, whilst the thinness of the metal blades does little damage to the cancellous tissue of the femoral neck. But it is well to remember that, however perfect in these respects the nail is, it has all the drawbacks of a metal foreign body. Apart from its undoubted virtue in fixing the fragments so that growth, union, and function can occur, it is essentially a check to tissue formation. When the pin is removed after weeks or months it is often found that the site in which it has lain is filled with loose bone debris or mere granulation tissue. In actual practice, even in cases which do well, the nail will have to be removed sooner or later, though this is a very trivial drawback when compared with the rapid immediate recovery which it usually brings about.

The Results

At present I do not think we have enough accurate information as to the ultimate results of the Smith-Petersen nail treatment. So far lists which have been published represent almost entirely only recent results, and I hope very much that subsequent speakers will be able to give us figures about cases at a year or more after the operation. I have seen cases in which the nail has been perfectly applied and the patients have been able to walk out of hospital, and yet in less than twelve months they have extruded the nail and suffered disunion, being left with an ununited fracture. I should very much like to know in what percentage of cases this disappointing result occurs. That it must occur in a certain proportion is obvious. Nailing the fracture will sometimes imprison a fold of capsule between the fragments, and no bony union can cross this fascial barrier. In other cases, even without interposition of capsule, new bone will be very slow in growing from the neck into the head and will be so feeble that it is quite unequal to bearing any strain. For both these reasons it is certain that failure must sometimes occur, and before long we ought to be able to state the probability of this mischance with some accuracy.

In the days when Whitman's method held the field the optimism of its originator at one time led us to think that it was well-nigh infallible. But when the pitiless light of experience was shed upon the facts it became obvious that only 50 or 60 per cent. of the cases gave bony union. Smith-Petersen's nail will probably give a better figure than this, but, for the reasons I have stated above, the percentage of successes must fall considerably short of 100. Probably 75 per cent. will represent the maximum number of ultimate successes. But even if this is the best that the method can achieve we have to remember that it will also have saved a great amount of suffering and invalidism in the rapid immediate recovery of function it has afforded to all of the patients.

Methods of Application

So far I have merely referred to the insertion of the Smith-Petersen nail without distinguishing between the different methods of its application. These may be grouped under three headings—namely,

1. The open operation.
2. Blind insertion over wire guides.
3. Blind insertion with the help of a mechanical director.

* Read in opening a discussion in the Section of Orthopaedics, including Treatment of Fractures, at the Annual Meeting of the British Medical Association, Belfast, 1937.

The Open Operation.—Smith-Petersen's original operation in this country has been modified by Watson Jones. The method was well described and illustrated in the July number of the *British Journal of Surgery* last year. In the case of comparatively young and robust patients this is the method of choice. It gives a good view of the fracture and enables the operator to draw aside the flap of capsule which so often is folded over the fractured neck of the femur. And, further, it allows an accuracy of reduction under the guidance of direct vision which is denied to any method guided only by the *x* rays. The insertion of a stout drill right through the neck and head and on into the acetabulum will hold the fragments in position whilst the nail is being driven into place. But, on the other hand, it is foolish to pretend that the open operation is either easy or free from danger. It must take nearly an hour in performance; there must be some loss of blood, and there must be a wide exposure of the soft parts and a free opening of the cavity of the hip-joint. For all these reasons I hold that it is unjustifiable in old and feeble patients. And it is just these feeble old patients who constitute the real problem in the wards of many hospitals, and particularly in the municipal institutions.

Blind Insertion over Wire Guides.—This method, which is associated with the names of Sven Johansson, Jerusalem, and King, has had a great vogue. We are honoured to-day by the presence of Professor Sven Johansson, and no doubt he will give us a convincing demonstration of its merits. I have watched it being done by various distinguished surgeons, including King, at Melbourne, who two years ago was an enthusiastic advocate of the method. We greatly regret that he is unable to come here to-day to introduce this discussion as he had hoped. Frankly I feel quite unable to do justice to the method, of which I have had so little personal experience. It involves two great drawbacks. First, it is long and tedious and involves keeping the patient for one or two hours under an anaesthetic. Secondly, it is dependent on taking and interpreting many *x*-ray pictures, on which reliance must be placed for guiding the nail into position. These drawbacks, to my mind, make it unsuitable for the feeble old patient whom I have already said is the real problem we have to treat.

Blind Insertion with Mechanical Director.—Instead of being solely dependent on the *x* rays to guide the Smith-Petersen nail into position various mechanical devices have been invented to secure accuracy of insertion. There are a host of these, and I will only speak of one which I have designed, and which has the great advantage of simplicity. It has been used many times by my friends Mr. Kenneth Pridie of Bristol and Mr. William Gissane of St. James Hospital, London, and I hope that they will be able to demonstrate to you its method and results. The fracture having been reduced, a two-pronged guide is placed over the line of the bones so that one prong touches the middle of the head of the femur and the other the base of the femoral neck. This enables a drill to be passed accurately into the bone in the true axis of the neck of the femur. Only a short incision is required; the operation is bloodless; it can be done under gas-oxygen anaesthesia; and if occupies only about ten to fifteen minutes. It is therefore suitable for the feeble old patient, who will suffer neither loss of blood nor shock.

After-treatment

The tendency nowadays is to give very little after-treatment, but to consider that the properly placed nail has cured the patient. Eversion of the leg is prevented by a bar fixed to the sole of the shoe, or by slinging the flexed knee to an overhead cradle. The patient is usually allowed up within one week, and walks with sticks or crutches, bearing no weight on the injured leg for about six weeks. I do not know why the tried and trusty walking calliper has been abandoned, but unfortunately it has. It seems to me that it would be much wiser to adhere to the use of this appliance as being a safeguard against weight-bearing until bony union is assured. The nail should be removed about three months after its insertion. It can do no further good, and its continued presence tends to produce bone atrophy.

Late Cases

Probably the number of cases of definite non-union will become much smaller as the practice of early and accurate nailing is more followed. But unfortunately there will always remain a certain number of these, and their condition, except in those who are bed-ridden, is so deplorable that it certainly requires attention. There are three possible operations by which pain and lameness may be diminished.

Bifurcation Osteotomy.—This is usually the method of choice. It is very simple and easy, involving no shock or haemorrhage. The femur is divided at the level of the small trochanter, and the shaft is pushed inwards so that its upper end shall impinge against the lower margin of the acetabulum. The leg is put up in moderate abduction and fixed in a plaster case. The objects achieved by the operation are two: first and foremost, the Y-shaped upper end of the femur will serve to support the weight of the body from the lower margin of the acetabulum, whilst the leg is brought more directly under the centre of gravity of the body; secondly, abduction of the leg is substituted for adduction, and therefore the shortening of the leg will be reduced.

Schanz's Cuneiform Osteotomy.—This is a more accurate method of reconstructing the line of the upper end of the femur. Two long stout pins are driven into the femur through a lateral incision. The upper pin goes through the great trochanter into the neck. The lower pin goes through the shaft of the femur several inches lower down. The two pins are inserted at a divergent angle, which represents the angle of reduction. A wedge with its base lateral is then cut out from the femur between the two pins. The femur is abducted until the wedge-shaped gap is closed. The projecting ends of the pins are incorporated in the plaster cast. The merit of this operation is that the upper trochanteric part of the femur is adducted by its transfixing pin. The reconstructed upper end of the femur is Γ-shaped (like an inverted L) and will actually support the separated head of the bone so that the weight of the body will force the two original fractured surfaces together. Böhler has recorded cases in which this has eventually led to bony union. The method is more difficult than the simple bifurcation osteotomy.

Whitman's Reconstruction Operation.—In this procedure the head of the femur is removed from the acetabulum. The neck is thrust into the hip-socket and the great trochanter is transplanted lower down on to the femoral shaft. The success of this operation will depend largely on the solidity of the damaged neck of the femur. If this is fairly sound it may be relied on to form a good substitute for the lost head. But this operation is not to be done in the case of feeble old patients, for whom the simple bifurcation osteotomy is the method of choice.

Conclusions

1. The proper use of a Smith-Petersen nail is the best ethod of treating intracapsular fractures of the neck of femur. Its simplicity and accuracy represent a great vance over older methods.

2. The Smith-Petersen nail is only the provision of an icient internal splint. Its great merit is that it allows the tient to get up within a few days.

3. The Smith-Petersen nail will neither ensure nor enurage new bone formation, and therefore there must ways be failures after its use.

4. The nail can only succeed if it is accurately inserted ter the fracture has been perfectly reduced.

5. The open operation is the method of choice in oung and vigorous patients.

6. For feeble old patients the blind method, using a iechanical guide for inserting the nail, should be used. his is easy and is free from danger.

7. In ununited cases a bifurcation osteotomy is usually ie method of choice.

OPERATIVE TREATMENT AND RESULTS IN FRACTURE OF NECK OF FEMUR*

BY

PROFESSOR SVEN JOHANSSON

Gothenburg

Hardly any form of fracture has attracted such interest and been the subject of so much discussion as fracture of the femoral neck, especially during the last few decades. The pessimistic feeling regarding its treatment has now given way to a more hopeful attitude. Authors differ, however, on this subject. As late as 1935 the well-known American surgeon, Kellog Speed, called this fracture "the unsolved fracture." With the greatest surprise, then, we hear that one of the leading surgeons of Germany, Professor Sauerbruch of Berlin, last year proposed removal of the head of the femur as a standard method in patients over 35 years, a method which I thought had been abandoned all over the world a long time ago.

The bad results have been thought to be due to the peculiar anatomical conditions in this form of fracture and to the high average age of the patients. The experience of the last few years, however, seems to me to have produced abundant evidence that this view must be abandoned. With the proper technique, consisting in exact reposition and good fixation, not too quickly removed, fractures of the femoral neck can be healed as easily as others. Everything, or nearly everything, depends on the technique. That the demands can be met and good results be attained with conservative treatment has been shown by Whitman, Lorenz, and Löfberg among others.

The Conservative Method

It is, however, not so easy to get a clear idea of the results to be attained by conservative treatment. The different statistics are scarcely comparable, for the reason, among others, that the cases have been selected for treatment particularly with regard to age. Concerning the end-results most of the statistics leave much to be desired. I think, however, that the American surgeon Gill comes very close to the truth when he says:

"Making due allowance for the faults of statistical tables, and granting that some surgeons, because of their greater expertness in manipulation and putting on plaster, may get better results than others, it is still evident that the use of the Whitman method has given vastly better results than the older methods of treatment, and that good end-results may be expected on a general average in 50 to 65 per cent. of cases."

In a critical review of various statistics of conservative treatment Gill estimates the primary mortality at not less than 20 to 25 per cent. In my own ward all cases were treated conservatively up to the year 1932. During the ten-year period 1922–31 the number of cases amounted to 390 and the mortality was 19 per cent. Concerning the end-results I can only say that they were worse rather than better than the average.

I have no experience of my own regarding the operative treatment entailing exposure of the fracture site, and for this reason will not discuss that method.

Extra-articular Osteosynthesis

In the method of treatment evolved by myself—extra-articular osteosynthesis, first published in the *Zentralblatt für Chirurgie* in 1932—three fundamental points demand attention: first, non-operative reposition by extension in the position of abduction with inward rotation following; secondly, fixation—without exposure of the fracture site—by the use of Smith-Petersen's rustless nail; thirdly, artificial impaction according to the method of Cotton. The following are the details of the treatment.

The reposition is done in bed with wire traction through the tibial tuberosity. In general, one week is enough to reduce the dislocation in the frontal plane. It is important that this primary wire traction take place with retention of the outward rotation, otherwise there is always the risk that the head will rotate. At the start I performed the reposition on an extension table as soon as possible after the accident; in most cases a satisfactory reposition was attained in this way, but not in all. Of my first 100 cases, in which as a rule the reposition was made on the extension table—redislocation took place in 16 per cent., necessitating a second operation; in the later seventy-nine cases, in which previous extension in bed was the rule, the corresponding figure was only 4 per cent. The advantage derived from the period of waiting is that the patient can be specially observed in regard to heart and lungs. Cases which are bad risks can be improved or eventually excluded. The only manœuvre of reposition which is needed on the extension table is inward rotation (about 25 degrees), of course with maintained extension. An abduction of about 45 degrees is enough.

Experience has shown that the reposition made in bed is not endangered by the removal of the patient to the extension table. Local anaesthesia and a few drops of ether while inserting the nail are enough if the patient has been given morphine beforehand. If spinal anaesthesia is used there is always the risk of an undesired over-extension. The reposition is controlled with *x*-ray pictures taken in two positions at right-angled planes; the position of the guiding wire and the nail is controlled in the same way. To simplify the insertion of the nail a thin stiff wire is first drilled into the centre of the femoral neck. After radiographs in two planes have shown the position of the wire to be satisfactory, the nail, which is bored through, is threaded on the wire. The wire is then withdrawn, and with a few blows on the femur-shaft below the trochanter the desired artificial impaction is effected. The most important point is to judge the direction accurately when introducing the wire. This is done in the following simple way.

* Read in opening a discussion in the Section of Orthopaedics, including Treatment of Fractures, at the Annual Meeting of the British Medical Association, Belfast, 1937.

About two centimetres below and parallel to Poupart's ligament are placed two rows of lead shot, each row consisting of three pieces. In this way the determination of the central point of the head in the frontal plane is greatly facilitated, it being possible to fix it within a millimetre or so. The point, when ascertained, is marked with a short hypodermic needle. In order accurately to locate the actual point of entrance for the guiding wire a sharp-pointed steel pin is inserted percutaneously just below the greater trochanter and radiographs are taken. The optimum point of entrance for the guiding wire, in both the frontal and the sagittal plane, is now easily calculable.

The required length of nail is ascertained in the following manner. The guide-wire is inserted for a distance of 9 cm., or, if the femoral neck is very short, 8 cm., and a skiagram readily shows whether the nail should be longer or shorter than the wire. Allowance must be made for the slight enlargement of the picture produced by the distance between the *x*-ray tube and the film. I once had the unfortunate experience of seeing a nail broken: the patient in question was unusually heavy. This kind of accident can be avoided, however, by using a nail with wings one millimetre broader than usual.

The position of the nail in the femoral neck is not a matter of indifference, since the forces of displacement that are compensated for by means of the nail are in a large degree dependent upon the situation of the fracture line. This fact was convincingly demonstrated as a mechanical problem by Pauwels in his work on fractures of the neck of the femur, published last year.

Owing to individual variability the axis of the femoral neck does not always assume a horizontal position upon 25 degrees inward rotation of the knee-joint, but by my method this does not much matter as the alignment apparatus I use permits a very satisfactory adjustment of the angle to the horizontal plane.

In the majority of cases I consider the axial location of the nail to be the best, for the simple reason that there is less risk of getting outside the femoral neck and head. Only in the cases in which the fracture line is almost vertical—uncommon cases in my experience—should one try to put the nail in the uppermost part of the neck.

After the operation the patient is placed in bed in a position of slight flexion at hip- and knee-joints, and remains there as a rule for at least one month. During this time treatment consists of mobilization of the limb, muscle massage, and stimulation by faradic currents. In order to avoid pulmonary congestion very old patients are allowed to *sit* out of bed at an earlier date, but any weight-bearing is absolutely prohibited. Thereafter one proceeds to walking exercises in a walking-chair. This continues for about a month, after which time the walking-chair is replaced by crutches—two at first and one later on. In uncomplicated cases, after about three months the ability to walk is usually quite good, and even full weight-bearing is painless. Observation by repeated radiographs is to be recommended as a safeguard against unpleasant surprises.

Should the position of the nail immediately after the operation or later prove unsatisfactory and redislocation occur one should not hesitate to reoperate. I have done so in nineteen of my 179 cases—that is, in about 10 per cent. In ten of these nineteen cases bony union took place. Redislocation has as a rule resulted from the use of the wrong technique; in some cases the nail had slipped on account of too early weight-bearing, in others the cause is not known. In twenty-six cases out of 179 the nail was extracted after it was certain that bony union had ensued (generally not before six months). The reason was in most instances that the nail had been displaced outwards and caused pain and aching.

A very important point is secondary necrosis of the femoral head. Here one has to differentiate between the healed cases and those not healed (pseudarthrosis). That the head in the latter cases should necrose is not surprising; in the former—that is, the healed cases—necrosis is, according to my experience, not very frequent. I have only seen it happen three times; in one case with very slight alteration and no clinical symptoms. On one occasion I performed arthrotomy and removed the necrotic part, which resembled typical osteochondritis dissecans. Even in cases treated conservatively one now and then observes necrosis. This is probably due to primary lesions of the vessels and not to the operation as such.

Partial necrosis of the head is more frequent in young than in elderly patients. In one of my cases, that of a boy 13 years old with a medial fracture, it occurred after the fracture had healed—a spontaneous epiphyseolysis.

Results

My own statistics now comprise 179 cases, most of them medial fractures. The classification has been according to Anschütz's scheme. The results are shown in the following table:

Medial Fractures

Age	Total Cases	Deaths	Cases Operated on	Complications				
				Non-union	Osteo-Arthritis of Hip	Aseptic Necrosis of the Femoral Head	Separation of Upper Femoral Epiphysis	Cases the Fate of which is Uncertain
Under 60	53	1	52	0	1	1	1	1
Over 60 ..	112 (66)	18 (15)	94 (51)	8 (5)	1 (1)	1		6 (6)
Totals ..	165 (66)	19 (15)	146 (51)	8 (5)	2 (1)	2	1	7 (6)

Intertrochanteric (Basal) Fractures

Age	Total Cases	Deaths	Non-union
Under 60	3	0	0
Over 60	11 (7)	0	0
Totals	14 (7)	0	0

The mortality was 10.6 per cent. Bony union followed in 95 per cent. of all cases alive, and in 94 per cent. of all medial fractures alive.
The figures in parentheses represent the number of patients in that group over the age of 70.

In one case only can the cause of death be attributed to the operation. This was a case of fat embolism. In nine cases the cause of death was found after full investigation not to be due to either the fracture or the operation. Fifteen patients out of the nineteen who died were more than 70 years old.

Time does not allow of an account of other statistics and comments on them. In passing I will only mention that, among others, Böhler and Felsenreich in Vienna, who used the method I have described, a short time ago published relatively large statistics showing the same favourable results.

Conclusions

My conclusions are as follows: By proper reposition and fixation bony union and fully satisfactory functional

results may be obtained in the majority of cases, even in medial fractures and in very old patients.

It is possible to obtain the fixation necessary for good union by means of the method of extra-articular osteosynthesis just described. This method is capable of wide application, because it is not necessary to put the patient in plaster-of-Paris afterwards—a fact which reduces the risk of mortality. The after-treatment is thus very much simplified.

The conservative treatment, as well as operative treatment with exposure of the fracture, should therefore be replaced by extra-articular osteosynthesis as the standard method.

PHYSICAL DISORDER IN 164 CONSECUTIVE ADMISSIONS TO A MENTAL HOSPITAL

THE INCIDENCE AND SIGNIFICANCE

BY

ROBERT J. PHILLIPS, M.B., B.Ch., B.Sc.

Late Assistant Medical Officer, Glamorgan County Mental Hospital

The existence of certain types of mental disorder which are caused by organic disease is too well known to need emphasis. Physical illness consequent upon mental disorder is equally well known. The extremely large number of physical disorders present in a series of consecutive admissions to the above hospital has indicated the need for an analysis in some detail of the types encountered, and a correlation, if any, between the mental and physical symptoms. This mental hospital serves a wide and thickly populated area, one which has suffered greatly owing to the industrial depression during the past few years. Hence a large number of the cases under consideration were admitted from what have been truly termed "distressed areas." This fact may be of significance as contributing, in the opinion of the author, to an abnormally high incidence of physical disorder in mental admissions.

Nature of Physical Disorders Encountered

Table I classifies in general terms the numbers of those admitted who have been or are suffering from medical, surgical, or gynaecological conditions. It also includes a miscellaneous group which will be described later, and a special group of cases termed "acetonuria" which are considered to be indirectly due to mental illness. From the table it is seen that of the 164 patients admitted 137 were found to suffer from some pathological lesion, but in this figure are included eight cases of senility (patients of 70 years of age or over) and seventeen of general paralysis of the insane. If excluding these, therefore, from the 164 admissions, 112 were considered to be physically unfit, a percentage of 68.

TABLE I

Total admissions	164
Medical conditions	61
Surgical conditions	20
Gynaecological conditions	8
Miscellaneous group	9
Senile cases	8
General paralysis of insane	17
Acetonuric group	14

These cases may also be classified under three distinct headings, dependent upon the connexion with the mental symptoms exhibited by the patient:

1. Patients whose mental symptoms are apparently the direct result of physical disorder—for example, arteriosclerotic dementia.

2. Cases in which the mental and the physical illness vary *pari passu* with one another. Thus, two females were admitted suffering from benign hypertension, and under treatment both physical and mental symptoms improved simultaneously. These cases will be described later in greater detail.

3. Patients with both physical and mental disorders which possess no apparent connexion with one another, and must be regarded as two distinct entities. These are well exemplified by cases with surgical conditions which could not be correlated with the psychoses of these particular patients. In the interests of clarity and detailed analysis it is of advantage to discuss these cases after classification according to the various systems affected.

Circulatory System

Of the total admissions twenty-nine were found to be suffering from some form of cardiovascular change, as shown in the following table:

TABLE II

	No. of Cases
Hypertension:	
(*a*) Benign	5
(*b*) Malignant	10
Valvular disease of the heart	9
Chronic myocardial disease	5

The cases of benign hypertension are of interest, being good examples of physical and mental disorder varying *pari passu*. Thus on examination three females were found to have an average systolic blood pressure of 190–200 mm. Hg in the absence of any renal lesions. The average age of these patients was 50 years, and consequently the condition might well be termed a "menopausal hypertension." Each patient exhibited similar mental symptoms—namely, nervous and emotional instability, being easily fatigued, readily upset by small everyday worries, and showing a tendency to hypochondriasis. Rest and the administration of bromide and theominal resulted in a simultaneous amelioration of both the physical and the mental symptoms in two of the three cases, with subsequent discharge from the hospital.

The patients with malignant hypertension constitute a fairly definite group in which the mental symptoms in most cases can be attributed to the physical disorder—namely, generalized arteriosclerosis accompanied by renal changes. Three of these were suffering from residual hemiplegia on admission. In six, whose ages varied between 56 and 65 years, the mental state was in the main one of confusion and restlessness, and although no cerebral accident had occurred before admission two died of cerebral haemorrhage during residence. The last case was that of a young male schizophrenic aged 30 years, who had a previous history of acute nephritis and whose physical state on admission was typically that of malignant renal arteriosclerosis. It is, however, realized that this group, which one is apt to class as arteriosclerotic dementia, may not be quite so clear-cut as one might infer, owing to the common incidence of arterial disease in mental patients even at comparatively early ages.

The nine cases of valvular disease of the heart included in this series exhibited no obvious relation to the type of psychosis present. Three of these patients were suffering from mitral stenosis, one of whom incidentally has since developed signs and symptoms of subacute infective endocarditis; three from mitral regurgitation; and three from aortic regurgitation. Again, in the five cases with physical

symptoms and signs sufficient to warrant a diagnosis of chronic myocardial degeneration no obvious correlation between the mental and the physical state could be discerned.

Respiratory, Alimentary, and Urinary Systems

Table III summarizes the various physical conditions met with in these groups.

TABLE III

		No. of Cases
Respiratory diseases	Lobar pneumonia	2
	Pulmonary tuberculosis	2
	Asthma	1
	Emphysema with chronic bronchitis	5
Alimentary diseases	Carcinoma of the stomach	2
	Visceroptosis	2
	Anorexia nervosa	1
Urinary diseases	Renal calculus	1
	Carcinoma of bladder	1

In none of the cases displaying signs and symptoms of pathological changes in the above was there a direct relation between the physical and the mental illnesses, with the possible exception of a case of lobar pneumonia and one of anorexia nervosa. In the former the early pneumonic condition present on the patient's admission was undoubtedly due to exposure, resultant upon his wandering about a mountain-side on a cold wet night in a confused state of mind. In the latter case of anorexia nervosa the patient was a female who, in spite of persistent efforts with oesophageal and rectal feeding, became progressively emaciated and died. During life she exhibited other hysterical phenomena, and was very emotional and depressed. A post-mortem examination revealed no organic cause for her persistent vomiting.

Haemopoietic System

The blood picture in the psychoses has stimulated a certain amount of interest. In the present series, however, the relation between the blood and mental conditions can only be indirect. Thus, of six cases, four suffered from severe secondary anaemia, one from simple achlorhydric anaemia, and one from acute lymphatic leukaemia. The four patients subject to secondary anaemia were all advanced schizophrenics, and it is suggested that the anaemia was consequent upon their extreme apathy and indifference to their physical existence.

Disorders of Metabolism

Nine of the total number of cases admitted were found to be suffering from some definite form of endocrine dysfunction. In view of the recent interest in the relation of the internal secretions to mental disorder (Langdon-Brown, 1936) these cases will bear close analysis. Table IV classifies the types met with.

TABLE IV

		No. of Cases
Thyrotoxicosis	Without exophthalmos	2
	With exophthalmos	1
Myxoedema		1
Diabetes		5

Symptoms of thyrotoxicosis occurred in three female subjects whose ages were 42, 36, and 35 years respectively, early exophthalmos being evident in the last-mentioned case. The clinical picture in each was typical, there being nervousness, thyroid enlargement, a warm skin, fine tremors, palpitation, tachycardia, loss of weight, irritability, and disturbed sleep. The mental picture was also common to all, outstanding features being depression, agitation, and emotional instability, with vague fears of incompetence. Here it is interesting to note that all three cases were of the voluntary class. Treatment with rest and Lugol's solution resulted in a marked simultaneous amelioration of both physical and mental symptoms. Improvement continued to such an extent that when they were discharged, at their own request, they were considered to be recovered. The author regards this relief of mental symptoms by the treatment of an apparent underlying physical disorder as of great significance, and worthy of further investigation in relation to mental disorder.

The case of myxoedema was that of a female aged 58 years who on examination was found to be of sallow complexion, lacking in energy, and slow of speech and cerebration; there was also loss of hair, dryness of skin, and a slow pulse rate. In addition her psychosis was of a chronic delusional type. There was a marked response to treatment with thyroid extract, and she is now fairly bright, energetic, and industrious, but the symptoms of the psychosis remain unaffected. It is thought, in this case, that apart from the mental retardation the physical disorder was unrelated to the mental disturbance.

Diabetes has long been recognized as being due to an impaired pancreatic function, characterized by glycosuria, hyperglycaemia, and a disturbance of carbohydrate, fat, and protein metabolism. Glycosuria and a sustained hyperglycaemia after the administration of glucose occur in certain states of emotional tension. Thus Derrien and Piéron (1923) report a marked increase of blood sugar in officers suffering from psychic disorders as a result of emotional shock, while Drury and Farran-Ridge (1925) state that the renal threshold for sugar is variable among psychotics. The latter two authors, Mann (1925), and others have demonstrated a sustained marked hyperglycaemia in these states, a fact which McCowan and Quastel (1931) have utilized to measure degrees of emotional tension objectively. These series of observations indicate some relation between emotional tension and diabetes, and it is not surprising to find that the five diabetics encountered in this series all showed various degrees of emotional instability. Treatment of the physical condition by means of diet, supplemented when indicated by suitable doses of insulin, resulted in a lowering of the emotional tension in three cases; one case remains unchanged, while the other patient died of myocardial degeneration. From the limited data at my disposal it seems reasonable to assume that mental symptoms may be associated with some chemical influence of the nature of a hormone or internal secretion, and that certain diseases of the endocrine organs may give rise to mental as well as physical upset.

Surgical Conditions

The varied forms of what one might term surgical cases are well shown by Table V.

TABLE V

	No. of Cases
Septic parotitis	1
Facial paralysis	1
Cut throats	3
Carcinoma of breast	1
Rodent ulcer	1
Inguinal hernia	2
Ventral hernia (post-operative)	1
Lumbar hernia (post-operative)	1
Dupuytren's contracture	2
Scoliosis of spine	3
Severe kyphosis of spine	1
Club foot	1
Fractured transverse processes of lumbar vertebrae	1
Acute intestinal obstruction	1

In six cases only can the physical and mental states be associated: (1) The acute septic parotitis occurred in a case of toxic-exhaustive insanity, the infection obviously being an ascending one from a dry foul condition of the mouth. (2) The case of facial paralysis occurred in a male who had attempted suicide by gunshot wound of the head. (3, 4, 5) Three cases of self-inflicted wounds of the throat were the result of acute melancholia. (6) The sixth case where one might correlate the mental and physical states was one in which a male sustained an injury to his back, *x*-ray examination revealing fractured transverse processes of the lumbar vertebrae. In this case the injury appeared to be a contributory cause to the man's state of depression.

Gynaecological Conditions

Routine examination of the pelvic organs was not carried out, except in cases exhibiting definite symptoms making such examination necessary. Thus it may be that a large number of minor gynaecological conditions have been overlooked, but nevertheless eight cases were admitted justifying the above heading, as indicated in Table VI.

TABLE VI

	No. of Cases
Puerperal fever	2
Mastitis	1
Menorrhagia	1
Severe leucorrhoea	2
Uterine prolapse	2

The two suffering from puerperal fever were obviously cases of puerperal insanity. The case of mastitis also occurred during the puerperium, but the patient's symptoms were more suggestive of the katatonic type of schizophrenia, the mastitis arising as a result of non-ability to suckle the child owing to the mental state. There did not appear to be any relation between the psychosis and pelvic disturbances in the remaining five cases.

Miscellaneous Group

Under this heading are grouped the following conditions:

TABLE VII

	No. of Cases
Severe acne vulgaris	2
Universal psoriasis	1
Mercurialism	1
Rheumatoid arthritis	1
Deaf-mutes	2
Post-encephalitic Parkinsonism	2

The cases of severe acne vulgaris occurred in epileptics who had been taking large doses of bromide prior to admission. The association appears obvious, and is further borne out by the fact that several other epileptics showed milder degrees of acne, also due in part to uncontrolled bromide therapy.

One case of universal psoriasis seems worth including in the series of physical disorders, although many other cases exhibited milder degrees of the same skin affection.

An interesting case of mercurialism occurred in a young male congenital syphilitic who, before admission, had been receiving mercurial inunction over a prolonged period. There was well-marked salivation, stomatitis, metallic smell, and offensive breath.

Rheumatoid arthritis was seen in one male suffering from severe agitated melancholia. Movement of joints was both painful and difficult, yet his extreme agitation made movement imperative—a triumph of mind over body!

The physical state of deaf-mutism was encountered in two male patients. In each the defect was congenital in origin. Both had been inmates of deaf-and-dumb institutions, where they had learnt trades and become useful members of the community. On discharge from such an institution one developed paranoid ideas, while the other became a shut-in personality leading an aimless and indifferent existence. It seems feasible to associate their physical affliction with their respective reaction types.

The physical and mental manifestations in the chronic form of encephalitis lethargica were clearly seen in two cases of Parkinsonism. Both were males, their ages 23 and 30 years, with a previous history of "sleeping sickness" at an early age.

Acetonuric Group

The occurrence of acetonuria, apart from that found associated with diabetes, in any recent admission to a mental hospital is of great interest. Fourteen out of the 164 patients whose cases are discussed here showed greater or lesser degrees of acetonuria on admission. A careful survey showed that all were in a debilitated state, with varying degrees of cachexia, exhaustion, cyanosis, furred and dry tongues, and foul stools. Their history before admission showed that they had invariably been "refusing food," were "extremely restless and agitated," or had been in a "stuporous confused state," taking but little nourishment. The inference is that all these patients were on admission suffering from a "semi-starvation state" resulting in an acidosis. Such a statement is fully corroborated by the fact that the acetonuria in all cases cleared within three to ten days following admission and treatment, the patients being more composed, taking their own nourishment or being artificially fed; the feeds contained appropriate quantities of glucose according to the severity of the case. Whilst the general symptoms resulting in the ketosis were similar, the psychosis producing the symptoms varied as illustrated in Table VIII.

TABLE VIII

Type of Psychosis	No. of Cases
Toxic-exhaustive insanity	3
Acute mania	2
Epileptic insanity	2
Agitated melancholia	1
Chronic melancholia	1
Chronic mania	1
Katatonic stupor	1
Benign stupor	1
Katatonic excitement	1
Senile dementia	1

These comments concerning the general incidence of ketosis in a variety of psychoses are of interest in view of the findings of Shaw (1920) and Thomas (1922), whose observations were limited to psychoses of the toxic and confused type. Such observations also emphasize the necessity for including an adequate supply of carbohydrate in the diet of patients who require artificial feeding, and as a general rule it has been found that the addition of about 3 oz. of glucose daily to the feed will counteract any danger of an acidosis.

Although seventeen cases of general paralysis of the insane and eight senile cases were admitted in this series, these are so essentially normal types of patient that it has not been deemed of sufficient interest to discuss them further or even to include them under the heading of abnormal physical states.

The diagnoses of the cases reviewed have when necessary been confirmed by the consulting staff of the hospital, by laboratory methods, by *x*-ray examinations, by operative findings, and, in a few, by necropsy.

Discussion

In this paper there is no desire to emphasize a "far-fetched" relationship between mental and physical disorders. The extraordinarily high incidence of physical illness among a series of recent admissions to this hospital, however, as indicated beforehand, has made necessary some analysis of the two types of illness. The facts here reported indicate that, in general, the physical and mental disorders are two separate entities, which require treatment as such. Thus if the cases here reported are reclassified as suggested in the early paragraphs, then the significance of any relation, or absence of it, between the two types of illness becomes very obvious. Such a classification is broadly given in Tables IX and X.

TABLE IX.—(*a*) *Cases in which there appears to be a Direct Relation between Mental and Physical States*

	No. of Cases
Anorexia nervosa	1
Puerperal fever	2
Arteriosclerotic dementia	9
Senile dementia	8
General paralysis of the insane	17
Post-encephalitic Parkinsonism	2
	39

Excluding those cases of general paralysis and senility, this total is much reduced—namely, fourteen.

TABLE X.—(*b*) *Cases in which there is an Apparent Association between Mental and Physical States*

	No. of Cases
Benign hypertension	2
Secondary anaemia	4
Thyrotoxicosis	3
Diabetes	3
Surgical cases	6
Mastitis	1
Acetonuria	14
Deaf-mutism	2
	35

In the remaining cases (ninety) there is no apparent connexion between the physical and the mental disease, which therefore must be considered as separate and distinct entities.

The factors responsible for the extremely large number of physical disorders encountered are not obvious. The types met with are too varied to formulate any general aetiological hypothesis to account for the high incidence. Few, if any, of the conditions met with could be explained on the grounds of previous family history: no reason can be given on epidemiological grounds. A partial explanation is that a number of the physical disorders are resultant upon mental conditions: thus patients, because they are mentally ill, neglect their physical well-being, with a consequent lowering of resistance. Another factor that does suggest itself as contributing greatly is the economic conditions of the areas from which these patients were drawn. There are insufficient data upon which to formulate a definite theory, but the fact that most of the males admitted to this hospital must be classed as permanently unemployed does suggest the possibility of malnutrition, with its consequent lowering of physical reserves with which to combat the physical strains imposed upon them as a result of their mental disorder. Evidence of malnutrition is afforded when it can be stated that the average weight on admission of the males in this series was nine and a half pounds below that of the average man. It was not possible to obtain the weights of all the females examined, but an analysis of fifty-one cases showed an under-weight of four and a quarter pounds. Average weights were calculated according to age and height, and compared with figures compiled by the Institute of Actuaries.

In a case presenting any mental abnormality the first essential is a thorough physical examination in order to discover the causal factors and if possible eliminate them. Too often it is assumed that the physical condition of a mental patient is good; thus the examination is far too brief and cursory. Hence it becomes apparent that the incidence of physical illness among the patients is a problem which every mental hospital must solve independently of and distinct from its main function, and one which it must, in respect of both resident and consultant staffs, equip itself to meet.

The value of a well-equipped laboratory dealing with the problems of bacteriology, pathology, and biochemistry is emphasized. The need for a "treatment centre," involving radiological service, operating theatre, dental department, equipment for heliotherapy, hydrotherapy, and electrotherapy, and a staff trained to deal with general as well as mental work, is well appreciated.

There is, indeed, an obvious need for a miniature general hospital, with all its numerous departments, within the organization of each mental hospital, and consequently a real necessity for a resident house-physician whose sole function would be the care of the bodily ailments of the patients. It is only when such a burden is removed from the shoulders of the resident mental medical officers that the problems of mental disorders, uncomplicated by other factors, can be fruitfully investigated.

I wish to acknowledge the keen interest taken in all the various aspects of this work by the medical superintendent, Dr. D. R. Owen, and in addition thank him for permission to report on the cases admitted to this hospital.

The fourth International Paediatric Congress will be held in Rome on September 27, 28, 29, and 30, under the presidency of Professor Spolverini. A discussion on neuropsychic diseases in paediatrics from the clinical and social points of view will be opened by Professor Jundell (Stockholm), Professor Glanzmann (Berne), and Dr. Allen of Philadelphia; Dr. Dingwall Fordyce of Liverpool will also take part. Mineral and water metabolism during early infancy and its relationship to artificial feeding will be discussed by Professor Noah Morris (Glasgow), Professor McQuarrie (Minneapolis), Dr. Spermasky (Moscow), and Dr. Czapo (Budapest). Problems of infantile tuberculosis will be considered in relation to (*a*) the modern study of the ultra-virus, (*b*) contagiousness on the part of the infant, and (*c*) prophylaxis and therapy. Professor Dufourt (Lyons), Professor Cohen (Brussels), and Professor Valtis (Athens) will introduce the first section, Professor Wallgren (Gothenburg), Dr. Kissel (Moscow), and Dr. Capon (Liverpool) the second, and Professor Noeggerath (Freiburg), Dr. Chester Stewart (Minneapolis), and Dr. Armand-Delille (Paris) the third. Visits to the paediatric institutions in the neighbourhood and to the monuments of Ancient Rome, and a tour of Naples, Capri, and Pompeii, extending over three days and following immediately on the conclusion of the congress, have been arranged. Further information may be obtained from Dr. Leonard Findlay (Secretary of the British Committee) and details regarding railway facilities and hotel reservations from C.I.T., 75, Regent Street, London, or other travel agencies.

RUPTURE OF THE PREGNANT UTERUS FROM INDIRECT INJURY

BY

GRACE STAPLETON, M.D., B.S.,Lond., M.C.O.G.

Professor of Obstetrics and Gynaecology, Lady Hardinge Medical College, New Delhi

As very few cases of rupture of the uterus from indirect injury, when advanced in pregnancy, have been recorded, it was thought worth while to report the following case.

Case Record

A Hindu primigravida aged 17 was admitted on February 20, 1937, to the Lady Hardinge Hospital, New Delhi, from a distant village. She was at full term, but had not come into labour, and the relatives were doubtful if the foetus was still alive, as the abdomen had been getting smaller since the patient had had a fall of some 12 feet from a first-floor veranda ten days previously. In other ways she was considered to have entirely recovered from the accident. The full history was not obtained till some days later; it was then said that she had lost her balance over a low parapet and fallen on her right side, being stunned for four or five minutes. She was picked up, and for the next few days stayed in bed. She complained of pain, mostly over the right loin and hip, and vomited several times, but this passed off gradually, and by the end of about five days she was able to get up and take food as usual. The bowels acted normally and she never complained of undue abdominal distension. She was seen by a doctor once, but he apparently found nothing very serious, and as the girl was recovering the relatives did not trouble to call him again. Foetal movements were thought to have been felt for three or four days after the accident, but the patient was not very sure. A blood-stained discharge was noticed four days before admission, and this had continued to a slight extent. Before this pregnancy menstruation had been regular and of the 3-4 30 day type.

CONDITION ON ADMISSION

The patient was a rather thin, slight girl with sallow complexion, and was fairly well developed for her age. Her mental condition was rather dull and she answered questions unwillingly. There was only slight anaemia. She moved about the bed easily and did not complain of any pain. The tongue was moderately coated; temperature 98.4° F., pulse 88, respirations 20. There were signs of bronchitis in both lungs, especially at the bases, but no complaint of cough was made.

The abdomen was enlarged with what appeared to be a full-term pregnancy in the left occipito-anterior position, with the head just over the brim, but no foetal movements could be detected and no heart sound was heard. No uterine contractions were felt. There was no abnormal distension or tenderness in any part of the abdomen.

On vaginal examination the os was seen to be closed and the cervix not taken up, and the presenting head could be palpated high up in the brim. The pelvis appeared quite normal in size. There was a little blood-stained discharge.

PROGRESS OF THE CASE

As there was no suspicion of ruptured uterus at that time, medical induction of labour with castor oil, quinine, and enema was tried. Two days later there were no pains and only a slight show, so she was re-examined, and as the cervix was still not taken up and a piece of membrane was felt protruding from it a laminaria tent was introduced and the vagina packed with gauze soaked in acriflavine and glycerin. The temperature was now normal and the pulse rate not above 90. The next day the pack and tent were removed and a douche given, and as the head bones of the macerated foetus could be just felt above the internal os three tents were introduced into the cervical canal and another vaginal pack inserted. The patient's general condition was unaltered and she still had no pains, but the pulse rate had risen to 98. The following morning—that is, the 24th—she was decidedly worse, though it was reported that she had had a fairly good night. For the first time there was some fullness and resistance at the sides and upper part of the abdomen, and she seemed anxious and nervous, though she would not acknowledge that she had any pain. The foetus was apparently in the same position. The pulse had risen from 116 at 6 a.m. to 148 at 10 a.m., and was very poor in volume; the temperature was 101°. The vaginal pack and tents were removed and, after douching, a finger was easily introduced through the cervix, but now the lower uterine segment was found empty except for the extreme edge of the placenta. Laparotomy was decided on, as evidently the foetus had been at least partially displaced from the uterus by the tents. On opening the abdomen by a median subumbilical incision the first thing encountered was the very macerated foetus lying free among the intestines, with the placenta low down on the left in front; the edge was still attached just inside the uterus, which was small, had a large gaping transverse tear right across the fundus, and had retracted and involuted in the shape of a cup. There was a little brownish free fluid in the peritoneal cavity but no sign of recent bleeding or general peritonitis; a small amount of lymph was present, however, round the pelvis, and the anterior part of the uterus was adherent to the bladder. As the patient's condition under the anaesthetic was very poor, the foetus and placenta were removed and the tear hastily stitched up with catgut and the wound closed after providing for drainage at the lower end. She was too ill to undergo hysterectomy.

After the operation her condition gave a good deal of anxiety as she developed pleurisy, followed by pneumonia, first at the base of the left lung and then in the corresponding position on the right side, and the signs persisted, though she complained very little of her chest. At first there was no abdominal distension and the wound seemed to be healing normally, but at the end of a week the edges began to fall apart, and later the whole wound gaped widely, as if the patient's powers of healing were at a minimum. She then began to show signs of partial intestinal obstruction, with vomiting on and off, but only a little distension. She seemed too ill to withstand another abdominal operation, especially as it was doubtful if the stitches would take. Another factor which had to be considered was that her relatives were ignorant peasants who would probably not only have refused to permit the operation if it had been suggested, but might have removed her promptly from the hospital and left her without medical aid and any hope of recovery. She was kept on rectal salines, which were retained well, and was given very little by the mouth except glucose water and fruit juice. A faecal fistula burst at the lower end of the wound on the eighteenth day after operation, and in two or three days she began to improve. The fistula healed spontaneously after eight days; her appetite then returned and she started to gain weight. The lungs were a long time clearing up, and did not become normal for quite another month. The abdominal wound also took a very long time to heal, but by May 11 the granulating area was only the size of a pea and the patient was discharged a few days later. By that time her general condition was good; her mental condition was quite bright, and she looked years younger than on admission.

The last vaginal examination was made on May 4, when the uterus was felt to be in good position and fairly normal in size and shape; the cervix was small and closed and the fornices were clear, but there appeared to be some adhesions between the fundus and the lower end of the abdominal wound.

Comments

On looking up the literature on uterine rupture one finds that from time to time cases due to direct injury, apart from labour and attempts at criminal abortion, have been recorded as well as a fair number of cases of so-called "spontaneous rupture," excluding those due to the giving

way of Caesarean and other scars. One can, however, find very few cases following severe indirect injury, although in some of the spontaneous cases a history of slight trauma or strain was recorded. DeLee (1933) states that only under the most violent indirect injury will a healthy uterus tear. According to the review by Kane (1923) the predisposing cause in multigravidae, apart from a clear history of previous uterine trauma or disease, appears to be thinning or hyaline degeneration of the uterine wall left from previous pregnancies, but in primigravidae some other reason must be looked for. It is suggested that some degree of infantilism may be present in certain cases that have no gross abnormality such as a poorly developed uterine cornu; but that is not very likely, as most patients in this class are sterile and menstruate scantily if at all regularly. In 1926 Riddell collected twenty reported cases of rupture during pregnancy; and among these no fewer than nine patients had had previous uterine disease and six had been subjected to instrumental intervention at some distant date, and only three were primigravidae. One-third of the total cases had terminated before the sixth month. In the present case there was no predisposing cause, as the patient had been free of uterine disease, and though she was rather young she had menstruated regularly for at least one or two years before conception, so it was unlikely her uterus was underdeveloped. In certain of the reported cases, such as that of Reeder and Moore (1935), the primary injury seemed to have been sufficient to cause a haematoma in the uterine muscle, and the onset of labour pains shortly afterwards completed the rupture and brought on acute symptoms of internal haemorrhage with shock. In this case, however, there was no history of labour pains, and so it must be concluded that the fall itself was the cause of the complete tear.

The classical clinical signs and symptoms of rupture of the uterus—that is, haemorrhage, external or internal, shock, and those of peritonitis following the death of the child—were conspicuous by their absence, though the patient had vomited, and had experienced enough discomfort to keep her in bed for a few days. In some of the published cases—for example, those of DeLee (1904), Green-Armytage (1913), and Gordon Ley (1920)—haemorrhage was very great, and in that of Green-Armytage led to death before there was even time for laparotomy. By the time the present patient came to hospital she had had only a small amount of toxaemia, and not until the tents had caused slight displacement of the head from where it had been resting on the widely open uterus did more acute symptoms arise. By itself the macerated foetus lying among the intestines was not sufficient to produce any general peritoneal irritation. There was also no evidence that she had had any marked internal haemorrhage, although the site of the tear, transversely across the fundus from one corner to the other, was almost exactly that shown in the sketch of Green-Armytage's specimen.

When treatment was considered there was the choice of either doing subtotal hysterectomy, which would have been preferable if the patient had been older, or of repairing the tear, keeping in mind, of course, the possibility of further pregnancy and the likelihood of the scar giving way again in the later months. In Gordon Ley's case of repair the patient did become pregnant again within a short time, and was successfully delivered normally at full term without any fresh uterine damage; but the risk is considerable, especially if the patient lives far from adequate medical aid. In the present case the uterine scar was not likely to be very satisfactory, as there was not time to trim the edges and stitch the tear in the usual layers owing to the patient's very poor condition on the table. She was only 17, and had not long been married, and though sterilization might have been performed her life would then have been miserable, owing to the social customs in her part of the country. She will therefore need very close attention should any sign of pregnancy again occur.

Difficulty in Diagnosis

The most difficult point in these cases is the diagnosis before operation. If there is much external bleeding without signs of peritoneal reaction accidental haemorrhage or placenta praevia is suggested, or if it occurs in the earlier months of pregnancy and the signs are mainly those of intra-abdominal haemorrhage, then a ruptured ectopic gestation or rupture of a poorly developed uterine horn may be the cause. Only in those cases in which the foetus can be felt without difficulty or moved under the abdominal wall is diagnosis easy. In this case, when the patient showed no signs of coming into labour after medical induction, and when no contractions of the uterine wall over the foetus could be made out clearly, the diagnosis of ruptured uterus was considered, but was thought most unlikely as she was a primigravida with tight abdominal walls, and the position of the foetus had remained as in an ordinary left occipito-anterior presentation, and she had seemed so well for the first three days in hospital. It was, however, the fact that the head of the foetus could be palpated easily through the fornices and, when the cervix was sufficiently dilated, through the os also, that had made one think such a diagnosis quite impossible.

Summary

1. A case of complete rupture of the uterus from indirect injury in a primigravida of 17 is reported.

2. Recovery occurred though operation was not performed until fourteen days after the injury.

3. Many of the classical signs and symptoms were absent.

4. Certain points in the aetiology, symptoms and signs, treatment, and diagnosis are considered.

C. J. W. Bisdom (*Maandschr. Kindergeneesk.*, May, 1937, p. 332) records two cases of alcohol and nicotine intoxication in infants. The first was a male infant, aged 8 days, the first child of a mother, aged 17, who had drunk a whole bottle of port (250 grammes) in the course of twenty-four hours. The symptoms consisted in a state of deep sleep from which the child could not be wakened for twenty-four hours, after which he became normal again. Alcohol was found to be present both in the mother's and infant's blood. The second case was a breast-fed infant, aged 6 weeks, the child of very nervous parents. The mother had been in the habit of smoking twenty cigarettes a day. The child's symptoms were restlessness, vomiting, diarrhoea, rapid pulse, and circulatory disturbances. Nicotine was found in the mother's milk. Symptomatic treatment was applied and the infant recovered.

EPIDEMIC OF PARATYPHOID B FEVER IN LIVERPOOL AND DISTRICT

BY

W. M. FRAZER, M.D., M.Sc., D.P.H.

Medical Officer of Health, City and Port of Liverpool; Professor of Hygiene, University of Liverpool

B. T. J. GLOVER, M.D., D.P.H.

Senior Assistant Medical Officer of Health, City of Liverpool; Lecturer in Public Health Administration, University of Liverpool

AND

V. GLASS, M.B., B.S., M.R.C.S., L.R.C.P.

Junior Assistant City Bacteriologist

On January 4, 1937, was notified the first of a series of cases of paratyphoid B fever in an outbreak which aggregated 132 primary cases before it was ended, of which 107 cases were in Liverpool, sixteen in the adjoining town of Bootle, seven in the rural districts surrounding Liverpool and Bootle, and two in North Wales. The quick succession of notifications—there were seventeen in the first week and thirty-three in the second week—and the widespread distribution in the city led to an immediate examination of samples of water from both Vyrnwy and Rivington supplies. The results were entirely negative, as indeed had been the results of the frequent routine bacteriological water examinations during the previous two months.

As the cases were notified they were charted on a graph according to their date of onset and entered on a map in accordance with the site of residence of the patients. Two features of the outbreak were quickly discerned—namely, that the majority of the cases had their date of onset at the end of December and beginning of January, and that the south end of Liverpool was escaping completely. One case notified from the south of Liverpool which appeared to be an exception proved to be one of pneumonia.

The history given by the majority of the patients showed that they obtained their milk and/or bread and/or butter, and sometimes other foodstuffs, from the same firm, hereinafter called firm A. Inquiries revealed that firm A traded through many retail shops over an area corresponding with that covered by the outbreak, and that the south end of Liverpool was supplied by an independent branch of the same firm, obtaining its food supplies from different sources. Further inquiry revealed that although some of the patients had eaten butter made by firm A, most of the butter they had purchased was of Empire or foreign origin, and had been delivered to each retail shop in the kegs in which it had been imported, there to be opened and sold in quantities to meet customers' requirements. Attention was therefore concentrated on milk and bread.

Firm A prepares pasteurized and sterilized milk, and sells approximately 8,500 gallons of the former and 1,000 gallons of the latter daily, approximately one-fifth of the milk consumed daily in Liverpool and Bootle. Out of 123 patients from whom a food history was obtained seventy-five consumed milk from this source. The pasteurizing plant is one of the latest design, and is under the regular supervision of the staff of the Health Department because this firm is one approved for the supply of milk to school children under the Milk Marketing Board's scheme. The processing and bottling arrangements are such that the milk is not touched by hand subsequent to pasteurization. It appeared, therefore, to be unlikely that the outbreak was attributable to this particular milk supply. Confirmatory support for this view was, first, that the children affected were not those who were attending the schools supplied by firm A except in a few instances, and, secondly, that the outbreak ought to have been a much greater one if it had been due to the infection of milk which was so high a proportion of the total milk consumed in the city. For these reasons attention was concentrated on the bread baked by this firm. Perhaps it is needless to add that in spite of this conclusion exhaustive inquiries were made into the recent health of the dairy employees, and that steps of a general nature were taken, such as additional care of the hands of the staff and so on.

Source of the Infection

The bakery is a very large one and is exceedingly well conducted. Out of 123 patients from whom a food history was obtained seventy-six (62 per cent.) regularly consumed bread from this source. The output is approximately a quarter of a million loaves a week. As this output is but a small fraction of the total number of loaves produced in Liverpool, the very high proportion of patients who ate this bread is significant. Both separated milk and water are used in baking, and although it was thought to be unlikely that anything added to the loaf before baking was the cause of the epidemic, inquiries were made into the sources of both. The water was city water stored in a tank. An examination revealed nothing of significance. The separated milk was efficiently pasteurized before use and was consequently above suspicion.

Observations were made during the night while the staff were carrying out their various duties, and it was noted that twenty employees were engaged in handling loaves after they had cooled, or were touching trays, etc., with which cold loaves would subsequently be brought into contact. It was decided to examine the blood of each of these twenty employees. The blood of five of them revealed the presence of agglutinins. Two had been inoculated with T.A.B. in the Army and in the Naval Reserve respectively, and their blood revealed the agglutinins usually found after inoculation. The blood of two others was positive to *Bact. typhosum* (H) 1 in 20. Lastly a male employee (G. E. T., aged 20), who had not been inoculated and who gave no history of illness like typhoid, either recent or remote, yielded a blood which gave a positive agglutination 1 in 20 to *Bact. paratyphosum* B (H), but was negative 1 in 20 to *Bact. typhosum* (H) and (O), and *Bact. paratyphosum* B (O), *Bact. paratyphosum* A (H), and the Salmonella group. This man was admitted to hospital under observation on February 9. He proved to be a carrier of *Bact. paratyphosum* B, the organism being recovered from both the faeces and the urine on the following occasions:

February	9	F−	U−
„	10	F−	U−
„	11 (*a*)	F−	U− (*b*) F− U−
„	12 (*a*)	F−	U− (*b*) F− U−
„	17	F−	U−
„	18	F−	U−
„	19	F−	U−
„	20	F−	U−
„	22	F−	U−
„	23	F−	U−
„	24	F−	U−
March	1	F−	U−
„	8	F−	U−
„	15	F−	U−
„	18	F−	U−
„	22	F−	U−

(*a*) and (*b*) refer to separate samples on the same day.

The patient was discharged from hospital on March 27.

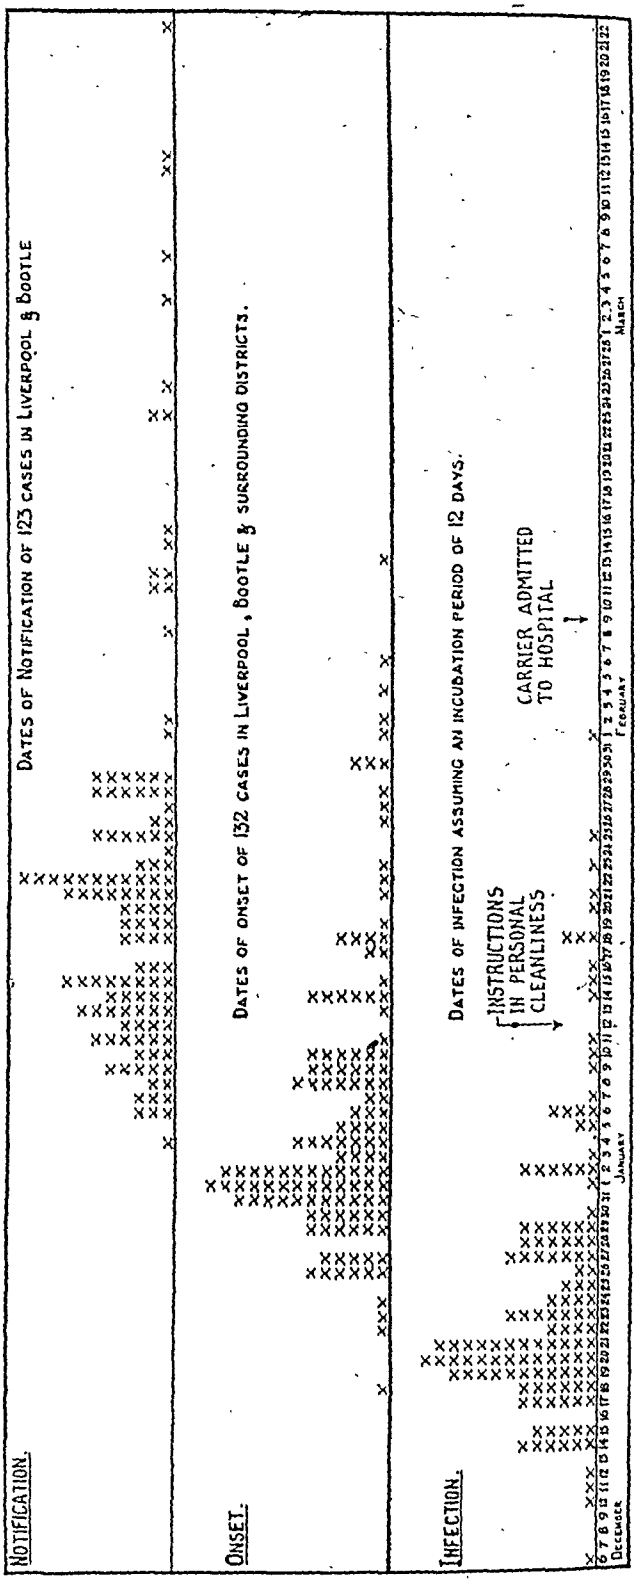
This carrier had been employed by the firm for two and a half years, for eighteen months of which time he had been handling bread after baking. Except for four days' absence with tonsillitis two years ago there was no illness which prevented him from working. He had had measles when a child, and the only other illness he could remember

was an operation on his elbow in May, 1933. Inquiries at the hospital where the operation was performed revealed that he was admitted for the investigation of a bone condition which was puzzling, looking neither like malignant disease nor ordinary osteomyelitis. The operation revealed a chronic osteitis of unknown origin accompanied by pus in which no organisms were found. In the opinion of the surgeon the condition was not incompatible with the belief that the abscess was of typhoid or paratyphoid origin.

The carrier had lived all his life with his father and mother. He is the eldest of six children, of whom the youngest is three years old. No member of the family gives any history of having suffered from typhoid fever or any typhoid-like illness.

Chart of Cases

The following chart shows the daily notification of 123 cases in Liverpool and Bootle in which the diagnosis was subsequently verified, the dates of onset of the 132 cases which occurred altogether, and a graphic representation of the dates of infection on the assumption that the average incubation period was twelve days. There appears to be a consensus of opinion that the average incubation period of paratyphoid fever is shorter than that of typhoid, though the variations in the incubation period of the former may be greater than those in the latter. For our present purpose the assumption of an average incubation period of twelve days is not unreasonable.



It will be observed that there were no cases with a date of infection subsequent to the admission of the carrier to hospital. At the same time it is noteworthy that the epidemic was waning for a month before his admission. There were 118 cases infected prior to January 8, and only fourteen between that date and February 9, when the carrier was admitted to hospital. This downward trend of the cases after January 8 may be accounted for partly by the increased precautions which were taken by the bakery staff in washing their hands after visiting the lavatory. It was on January 12 that special instructions were given to the staffs of both the dairy and the bakery in regard to this matter. If this carrier was in fact the cause of this outbreak, contaminating the surface of loaves with infection on his hands, it appears to be necessary to assume that the degree of contamination diminished with improvements in personal cleanliness; it may also be necessary to assume that the excretion of organisms in the urine and faeces was intermittent and variable in amount, an assumption not unreasonable in view of the intermittency of excretion during his sojourn in hospital. Unfortunately no attempt was made to estimate the number of the organisms he was excreting. There is a record, however, that a faecal specimen on February 11 yielded no organisms on direct plating, but that they were found after enrichment. The number of organisms in this specimen must therefore have been small.

Another feature of the chart is that 111 cases had been infected (assuming an incubation period of twelve days) before the first notification was received (January 4), leaving only twenty-one cases to be infected subsequently. The infection had reached the great majority of the patients before its existence was suspected.

The age and sex distribution of the cases is as follows:

Age ..	Under 1	1+	5+	10+	20+	30+	40+	50+	70+	Totals	
Males..	2	8	18	17	11	4	5	1	1	67	132
Females	1	6	10	20	11	6	6	5	0	65	

The even distribution between males and females, not only in the totals but also at different ages, suggests infected food which is consumed by all, irrespective of age and sex. Bread as the infected food is not incompatible with this. Of the three children under 1 year who were regarded as cases, two were doubtful. The one in which the diagnosis was confirmed by finding the causal organism was a patient whose parents had given it crusts to chew from bread derived from firm A.

Value of Faecal Cultures in Diagnosis

In a paper to be published shortly by Professor H. D. Wright, the city bacteriologist, and one of us (V. G.), detailed reference is made to the value in diagnosis of faecal cultures at different stages of the disease. Out of 124 cases in respect of which there was information on this point, 83 per cent. of the faecal specimens submitted for examination during the first week of illness were

positive. The corresponding figures for the second, third, and fourth weeks of illness were that 94.2 per cent., 92 per cent., and 87.5 per cent. respectively of patients had positive stools. In the case of patients in their fifth week of illness all the faecal specimens were positive. The corresponding figures for the sixth and seventh weeks were 75 per cent. and 77.7 per cent. respectively. The isolation of the causal organism from the stools is of great value in diagnosis even so early in the illness as the first week, and even so late as the seventh week there is a good chance of isolating the *Bact. paratyphosum* B from the first specimen of faeces submitted. Another interesting feature to which attention is called in the paper alluded to is the rate of disappearance of *Bact. paratyphosum* B from the faeces. Fifty per cent. of the patients presented positive faeces in the seventh week of illness and 20 per cent. were still excreting the organism in the ninth week.

An attempt was made to determine the survival of *Bact. paratyphosum* B on bread crusts. Three experiments were done with the strain isolated from the carrier. A slice half a centimetre thick was cut off the end of a fresh paper-wrapped loaf. This was cut into small rectangular pieces 1/2 × 1 cm., which were placed in dry sterile Petri dishes with the crust uppermost. Each crust surface was smeared with a loopful of a saline suspension containing a known number of organisms from an agar culture. The fluid disappeared into the substance of the crust remarkably quickly. The Petri dishes containing the inoculated crusts well separated from one another were stored in a dark cupboard at room temperature. At various intervals after inoculation a piece was removed from the dish and dropped into a tube of tetrathionate broth, any growth subsequently being fully identified serologically. With an inoculum of four million organisms *Bact. paratyphosum* B was recovered from the crust on the seventeenth day but not on the twenty-second or twenty-third day. When only 120 organisms were employed recovery was possible on the sixth day but not on the seventh or twelfth day. In another experiment with six million organisms from a broth culture the crusts still yielded cultures on the thirty-third day, by which time the material under examination was exhausted. It was not possible to be satisfied that any actual multiplication of the organisms occurred in the crust. It is evident that they can remain alive for a considerable time.

Tests to determine the similarity of organisms from patients in the epidemic were undertaken. M. Kristensen and K. Bojlén (1929) have proposed to differentiate five groups of *Bact. paratyphosum B* according to the rate of fermentation of rhamnose, the fermentation of inosite, and behaviour in the Bitter test (1926), which is also dependent on rhamnose fermentation. These tests were made on ninety-five strains from forty-eight cases (including the carrier). All strains fell into the same group, Kristensen and Bojlén's group R_1I_1, the features of which are that inosite is readily fermented, rhamnose slowly, and the Bitter test is negative. Eight other strains from four cases not associated with the epidemic fell into the same group.

Course of the Illness

Eighty-seven cases were treated in the Fazakerley Fever Hospital, and the following observations are from notes supplied by Dr. A. E. Hodgson, the medical superintendent. With a few exceptions the course of illness was uneventful and free from severe symptoms. Forty-one patients (47 per cent.) exhibited a rash and two had intestinal haemorrhage. There was no example of perforation of the intestine. It was noteworthy that in children the onset was abrupt, with abdominal symptoms simulating an "acute abdomen." In three cases the carrier state persisted for a long time. In one case (J. P., female, aged 57 years) the date of onset was December 26, 1936, and organisms were isolated from the faeces so late as June 19, 1937. This patient was still in hospital on June 21. The second case (H. W., female, aged 38 years), with date of onset January 3, 1937, was a carrier until May 26. The third case (H. N., female, aged 42 years), with date of onset January 9, developed cholecystitis. The gall-bladder was drained and *Bact. paratyphosum* B was isolated (June 5) from the pus.

The part played in diagnosis by bacteriological examination was a prominent one. Out of the 123 cases occurring in Liverpool and Bootle the causal organism was recovered from 111 patients, these specimens being examined in the city laboratory in 109 instances. Of the other twelve cases the diagnosis was confirmed by serological examination in nine instances. In three cases only was the diagnosis made on clinical grounds alone.

There were eleven deaths among the 123 cases in Liverpool and Bootle, a fatality rate of 9 per cent.

Summary

1. An outbreak of paratyphoid B fever occurred in Liverpool and Bootle at the end of 1936 and beginning of 1937, with 123 cases and eleven deaths. An additional nine cases in rural districts were also considered to be connected with this outbreak.

2. The circumstances of the rise and decline of the epidemic were not incompatible with the belief that it was due to the infection of loaves of bread handled by a carrier of *Bact. paratyphosum* B who was discovered in a bakery from which was derived the bread consumed by 62 per cent. of the patients.

3. The isolation of the causal organism from the stools of patients proved to be a great aid to diagnosis so early in the illness as the first week. Even as late as the seventh week there is a good chance of isolating the organism.

4. Fifty per cent. of the patients presented positive stools in the seventh week of illness, and 20 per cent. were still excreting the organism in the ninth week.

5. Ninety-five strains of *Bact. paratyphosum* B isolated from forty-eight patients all fell within Kristensen and Bojlén's group R_1I_1.

6. The survival of *Bact. paratyphosum* B on bread crusts was established. A heavy inoculum (6 million organisms) survived at least thirty-three days, an inoculum of 4 million organisms survived seventeen days, and a light dosage of 120 organisms was recovered on the sixth day.

7. With few exceptions patients made uneventful recoveries. Forty-seven per cent. exhibited a rash. In children the onset was abrupt with abdominal symptoms simulating an "acute abdomen." Three cases, all adult females, persisted as carriers for five months or more.

Acknowledgements are due to the city bacteriologist (Professor H. D. Wright) for the bacteriological information contained in this report: to Dr. Hodgson, the medical superintendent of the Fazakerley Isolation Hospital, for clinical details; and to the medical officers of health of Bootle, Waterloo and Seaforth, Whiston, West Lancashire Rural District, Great Crosby, Litherland, Huyton, and the Caernarvonshire Combined Sanitary Districts for information relating to cases which occurred in their districts.

G. W. Ronaldson (*Brit. J. Child. Dis.*, April–June, 1937, p. 99) records two personal cases of morbilli bullosi, one of which was a girl, aged 4, and the other a female infant, aged 10 months, who died. He classifies the reported cases of bullous measles as follows: (1) pemphigus with a morbilliform eruption; (2) true bullous measles—that is, cases of measles with anomalous elements; and (3) the association of measles and pemphigus.

Clinical and Scientific Proceedings

AETIOLOGY AND TREATMENT OF DUODENAL ULCERATION

At a meeting of the Fife Branch of the British Medical Association Mr. J. J. ROBB gave an address on "The Aetiology and Treatment of Duodenal Ulceration."

Discussing the historical aspect of treatment of this condition Mr. Robb said we had passed from a position of comparative satisfaction, based on successful cases without due regard to the number of failures, to a more critical attitude, owing to the persistence of failures and lack of definite knowledge as to the cause of ulceration. When he began research into this subject he found that the study of failures gave little help, and that it was only by making an accurate study of the normal that some understanding of the abnormal was ultimately reached. His investigation of gastro-intestinal function was made by *x* rays, fluorescent screen, and barium meals. Radiographs were only useful where they showed an actual abnormality of organic nature.

Although the stomach was an extremely sensitive and powerful organ, responding to the mental state of the patient, to satisfaction and dissatisfaction, by changing its position, rising or falling, it was quite clear that a resting normal did exist. With the patient erect the normal stomach swept downwards from the cardia until the greater curvature just touched a line joining the iliac crests. From there it rose steeply to a fixed position at the pylorus. This was the normal or sthenic stomach, and permanent departures from this position were abnormal, either above—hypersthenic—or below—hyposthenic.

The lecturer then reviewed normal gastro-intestinal function, showing that hypersecretion was exaggerated normal, whereas hyposecretion was abnormal and the result of failing function. The nerve supply to the stomach and intestines, he continued, was by two groups, both autonomic: (1) the intrinsic group consisting of the plexuses of Meissner and Auerbach; and (2) the extrinsic group formed by the vagi, the coeliac, and the presacral plexuses. The intrinsic group controlled all normal bowel function, and, apart from the region of the pyloric sphincter, were motor throughout. The extrinsic group, apart from the vagi, exercised control over intrinsic function, either locally or throughout the whole tract, evidence of this group's activity being shown by dilatation of bowel and hypertonicity of sphincter. The exact function of the vagi was uncertain, but the abdominal sympathetic system and the vagi did not function in sympathy with each other. Stomach function appeared to continue in oblivion to changed function in intestinal areas.

Aetiology

Cases exhibiting the well-known symptoms constituting the duodenal syndrome might or might not show actual ulceration. Nevertheless, clinically and therapeutically they were inseparable, and should be placed in one group with ulcer as an additional sign. Examination of these cases by investigation of bowel function by barium screening showed a definite distortion, although the actual appearance of this distortion might be masked by the mental state of the patient at the time or even by the presence of the barium changing the visceral state. Patience on the part of the investigator and the complete confidence of the patient were required. In the early case departure from the normal showed itself by overactivity and hypertonicity of the stomach indicated by the raising of that organ far above its normal active level. In the more advanced case this overactivated stomach began to tire and dilate; it sagged down, and might ultimately lie low in the pelvis. Maximum irritability and overactivity occurred at from one-half to one and a half hours after ingestion of food, depending on the nature of the food ingested, the power of the stomach musculature, and the degree of hypertonicity in the pyloric sphincter.

The lack of opening response at the pylorus showed that the normal chemico-physical basis for the stomach evacuation reflex had vanished and other reflexes had taken control of the pylorus. This fact was not appreciated by the stomach, which intensified its efforts to evacuate its contents, and with a hypertrophied muscle these efforts were remarkably successful, a forced evacuation of contents taking place through a tense pyloric sphincter at a rate above normal. These contents, ill digested and saturated with an overabundance of free acid, were driven through the central and weakest part of a hypertonic and fixed sphincter and impinged forcibly on one area of duodenum, an area, therefore, which showed, sooner or later, a chronic traumatic inflammation with its sequelae of congestion, fibrosis, central anaemia and degeneration, and the formation of ulcer. Further signs of sympathetic agitation appeared along the bowel—duodenal stasis, delay at duodenal-jejunal flexure and at the ileo-caecal valve. In the early case the colon was spastic, later flaccid, dilated, and dropped.

Abdominal Sympathetic Activation

These departures from the normal functioning of stomach and bowel, showing the origin of a duodenal ulcer, were evidence of a syndrome of sympathetic activation. Sympathetic activity was always protective and sought to obtain immobilization and rest. Therefore the purpose of this sympathetic interference or syndrome was to slow down bowel movement and transport. The stomach only remained oblivious to this demand for rest as it held the key to tissue life and must function to deliver sustenance to the regions of digestion and absorption. This effort on the part of the stomach and counter-effort by the abdominal sympathetic resulted in the maintenance of a fine balance between the danger to life from some lesion and the danger of insufficient nutrition. We had now ceased to regard the ulcer as a primary disease or the stomach as being at fault. The real disease lay in the activated abdominal sympathetic system, and the next step was to find out the cause of this activation.

Bearing in mind, Mr. Robb continued, that the ultimate function of the autonomic system was the preservation of life, we could understand the action of the abdominal sympathetic endeavouring to protect the body against some dangerous lesion. This action may be excited centrally or through peritoneal irritation. Here we regarded the peritoneum and serous linings generally as forming, in addition to other purposes, a third element in the system of defence against disease by awakening the appropriate sympathetic system, thus bringing about attempted tissue immobilization leading to disturbed function.

The causes were classified as primary and secondary: the primary group, where the cause was central or psychological; the secondary group, including all tissue lesions which might affect the peritoneum. It was important that all secondary causes should be excluded before the primary group was considered. This primary group included all psychological disturbances leading to repression or dissatisfaction or psychophysical conflict in relation to environment or employment. The discovery of the cause did not mean cure, as established ways of life could not be changed radically. Nevertheless, a holiday or isolation in a nursing home might effect a complete, if temporary, cure without other treatment.

The secondary group were divided into intra- and extra-abdominal. The commonest intra-abdominal cause was chronic appendicitis. Other causes were tuberculous adenitis, peritoneal and omental bands, and, in the female, chronic inflammatory states in the pelvic organs. Chronic cholecystitis only acted as a cause when the inflammatory process involved the peritoneal covering. Chronic diverticulitis of the colon was probably a cause in one case. Extra-abdominal causes included any lesion producing a chronic toxaemia or bacteriaemia.

Treatment

Treatment might be symptomatic or direct. Symptomatic treatment was easier and was the method which so far had received most attention, but the end-results were not satisfactory. Direct treatment was more difficult for doctor and patient, but the result was definitely better. If this interpretation of the aetiology was correct, Mr. Robb continued, then we had to think of duodenal ulcer as a late symptom in the disease. Therefore, if we could begin treatment early, when there was probably only a little dyspepsia and constipation, a duodenal ulcer would not appear. The logical sequence of treatment would appear to be first to remove the cause of the sympathetic upset within the abdomen, and, secondly, to correct disordered bowel function. As the abdominal sympathetics were in health quiescent but once activated became in time abnormally active, removal of the cause did not always cure, and in late cases especially further measures were required to produce normal quiescence.

In doing this the stomach could be disregarded. The chief difficulty was the pyloric spasm and the spasm of the junctional sphincters, and, secondly, imperfect motor function of the intestines due to sympathetic interference. The sympathetic stimuli must be allayed or cut out either by atropine, over a period of six months to two years, or by bromide. Atropine, owing to the production of symptoms of poisoning and the discomfort caused by eye symptoms, was inferior for this purpose to bromide, which, in small doses—5 grains thrice daily—was found by screen tests to produce the necessary results provided a low chloride diet was taken at the same time. With this small dose there was no risk of bromide poisoning. The next step was gently to encourage the bowel to get back to its natural rhythm. The use of strong purgatives was avoided, as overactivated peristalsis reawakened the sympathetic syndrome in spite of bromide action. The reaction of each individual case had to be carefully studied. Medicine and re-education were both required, and the most effective drug for this purpose was mag. carb. pond., 20 grains thrice daily. Finally, to aid in stabilizing the sympathetic system, the lecturer gave calcium lactate or carbonate in doses of 6 to 8 grains daily. As regards diet, any foods which had a violent forward peristaltic action should be avoided, and, if ulcer is present, nothing should be given that was hard or tough to traumatize and prevent healing. Therefore, red meats or any very highly flavoured dish should be avoided. Hunger should also be avoided, so that feeding should be at frequent intervals.

Scope of Surgical Treatment

The scope of surgery in treatment, briefly, included those cases in which definite hypofunction had been established and in which medical measures, therefore, could not alone bring the stomach back to normal. Its purpose was to make the course of digestion fit in with the abnormal conditions produced by hypofunction. A gastrojejunostomy provided an efficient drain from the lowest part of the stomach, and was the best procedure. Where stomach muscle failure was early and pyloric function was unimpaired but a large and active duodenal ulcer was present, direct anastomosis of the stomach to the second part of the duodenum seemed most satisfactory. Where stomach and duodenum both showed signs of muscle failure, gastrojejunostomy and duodenojejunostomy were each required.

The only justification for surgical treatment was muscle failure. Success following operative treatment might be deceptive, as shock of operation alone might allay sympathetic activity from two months to two years. Therefore, medical treatment, as already indicated, should always be continued after operation. No therapy could successfully deal with cases of duodenal ulceration unless it took into account the reason why the ulceration was there, and the fineness of the mechanism that regulated all gastro-intestinal movement and function.

Clinical Memoranda

Typing of C. Diphtheriae in Connexion with the Clinical Course of Diphtheria Infection*

During 1934 and 1935 the type of bacillus present in ninety-one patients and ten carriers was investigated. The accompanying table shows the relation of the various types to the severity of the disease. The "gravis" type was not predominantly found in severe cases, whereas the percentage of "mitis" was high.

Period	Clinical Course	Total No. of Cases	Gravis	Intermedius	Mitis	Atypical
1934 and 1935	Lethal	10	1	2	6	1
	Very malignant	12	1	7	4	—
	Medium malignancy	26	2	9	15	—
	Mild	43	1	10	30	2
	Carriers	10	1	—	9	—

Budakoff, Golinevitch, Undrevitch, and Jer-Osipora (1936) could not find any constant relation between the severity of infection and the type of strain present, though they did note that the "gravis" type occurred more often in fatal cases of illness.

In the special observation of twenty patients treated with serum we gained the impression that the majority of those who showed no improvement after the administration of antitoxin yielded the "mitis" type. Among the whole of the strains we studied twelve (one "gravis," three "intermediate," and eight "mitis") were avirulent when tested on guinea-pigs according to the Eagleton and Baxter method.

We do not consider our results at variance with those described by Anderson and other authors, for a final conclusion can be reached only after investigation on very large numbers of cases of diphtheria observed during different epidemic phases of diphtheria epidemics. Our work indicated that at a period when little diphtheria occurred, and most of it mild, the "mitis" type of bacillus was most often met with, whereas during a serious epidemic the "gravis" and "intermediate" types became more frequent.

SUMMARY

1. Cultures from ninety-one patients and ten carriers yielded 63 per cent. "mitis," 28 per cent. "intermediate," and 6 per cent. "gravis"; 3 per cent. of the strains were atypical.

2. We could not find any close relation between the severity of the attack and any special type of bacillus.

3. Twelve strains avirulent for guinea-pigs were isolated.

4. In non-epidemic periods the "mitis" type is found most frequently.

Spontaneous Pneumothorax Occurring with the Onset of Labour and Resulting in Sudden Death

The following case seems to be of sufficient interest to merit being placed on record.

CASE HISTORY

Mrs. B., aged 30, primipara, was admitted to the Leeds Maternity Hospital on January 15, 1937, for investigation following a severe attack of abdominal pain. The history was one of very good health until a febrile illness in December, 1936, since when she had complained of cough, malaise, loss of weight, and intermittent attacks of left-sided abdominal pain. Her general condition was poor, and there was slight instability of the temperature and pulse. Physical examination, together with a skiagram of the chest, revealed bilateral apical tuberculosis with an extensive effusion at the left base. She was about twenty-four weeks pregnant.

The patient was transferred to Killingbeck Sanatorium on February 17, where she remained until term. From the time of admission she improved rapidly and steadily. The cough soon disappeared, and never at any time did she have sputum. After a month of sanatorium treatment she was allowed out of bed, increasing her time to a maximum of four hours daily. On this latter grade her temperature and pulse kept within normal limits Pregnancy was normal in every way, except that the foetal head remained above the pelvic brim until term. This was attributed to an occipito-posterior position as there was no disproportion. At term it was thought advisable to induce labour, and she was accordingly returned to the Leeds Maternity Hospital on May 4, 1937. On the day of transfer her general condition was very good indeed. Physical examination revealed an impaired note with a few crepitations at each apex, and dullness with diminished air entry at the left base.

A medical induction was given on May 4, and the head became fixed though labour did not commence. The induction was repeated on May 6, and the patient started to have slight pains at 7.30 a.m. on May 7. She was then extremely well. Half an hour later she suddenly collapsed, having marked cyanosis and dyspnoea, and died within two minutes, before medical assistance arrived.

A post-mortem examination was made on the morning of death. The right lung was completely collapsed, and on inflation of the trachea air escaped from a perforation, about a quarter of an inch in diameter, on the surface of the middle lobe. Further examination showed that the perforation was over the site of a small subpleural abscess. Apart from healed tubercles at the apex and some calcified nodules in the middle zone, the remainder of the lung was normal. There was partial collapse of the left lung due to a thick adherent pleura which had obliterated the pleural cavity. Both upper and lower lobes contained healed and active tubercles. Apart from engorgement of the right side of the heart all the other organs were normal. The cervix was taken up but not yet dilated.

SUMMARY

A case is described of a patient who came under observation for pulmonary tuberculosis midway through pregnancy. At term she was very well, with little evidence of active disease.

Half an hour after labour commenced she had a spontaneous pneumothorax on the less affected side, and died within the unusually rapid time of two minutes.

We are much indebted to Dr. W Santon Gilmour, medical superintendent of Killingbeck Sanatorium, Leeds, and to Mr. D. W. Currie, honorary obstetrical surgeon to the Leeds Maternity Hospital, for permission to publish this case, and for their help and advice.

Reviews

CHRONIC FLUORINE POISONING

Fluorine Intoxication. A Clinical-Hygienic Study. By Kaj Roholm. (Pp. 364; 96 figures. 20s. net.) Copenhagen: Arnold Busch. London: H. K. Lewis and Co., Ltd. 1937.

In a short review it is impossible to do adequate justice to this important, interesting, and able piece of research. The author is a Danish physician who has been attached to the Factory Inspectorate in Denmark for the purposes of this work. The book opens with a comprehensive review of the part played by fluorine in biology. Intoxication in man, in plants, and in animals, the occurrence of fluorine in animate and inanimate nature, the effects of fluorine upon protoplasm and enzymes, the effects of acute, subacute, and chronic fluorine intoxication, are some of the most important parts of the first section. There follow descriptions of the technique adopted in the author's investigation, of his study of spontaneous cryolite poisoning, and of his own experimental investigations on rats, pigs, calves, and dogs. The book concludes with an able discussion of the whole problem of fluorine intoxication and with a presentation of his own conclusions.

The whole book appears to be so important that every effort should be made to bring it to the notice not only of industrial and general branches of the medical profession, but also of radiologists, public health officers, dentists, veterinary surgeons, and agriculturists. In the present review it is proposed to confine attention to a brief account of Dr. Roholm's conclusions concerning chronic intoxication with fluorine. In passing we may offer a word of praise to the author for his remarkable command of the English language, and to the printers for the excellence both of the type and of the illustrations. The reproductions of the *x* rays are particularly successful.

Chronic fluorine intoxication was first recognized by Flemming, Moller, and Gudjonnson among the workers in a cryolite factory in Copenhagen in the year 1932. Cryolite is sodium aluminium fluoride ($AlF_3.3NaF$), a rare mineral mined only in South Greenland. Its industrial use, which is widespread, depends upon the ease with which it causes a flux when heated. Cryolite is used in the smelting of minerals (especially aluminium) and in the manufacture of enamel and glass. The crude ore is mined in Greenland and shipped only to Copenhagen and Philadelphia. Chronic fluorosis occurs among those who mine, and, especially among those who handle, the ore in its crude state. If the risk of chronic fluoride poisoning were confined to those who handle cryolite and those who are exposed to its fumes, English hygienists would need to take little interest in the subject of chronic fluorosis. But other earth-containing fluorides are used in industry and commerce. The most important of these are fluorspar and fluoride-containing clays. Whenever these natural products are subjected to a high temperature fluorine or fluoride-containing gases are discharged into the air unless special precautions are taken. These substances may prejudicially affect plants, animals, and men. Furthermore, since compounds containing fluorine are used for such purposes as the preservation of food, the killing of insects, and the etching of glass and the cleaning of china ware, there are real grounds for concern lest unrecognized cases of chronic fluorine poisoning may be occurring in this country.

Dr. Roholm mentions the following industries in which exposure to fluorine-containing gases may occur. (It is to be noted that the brunt of the exposure may fall not upon the workers but rather upon those who live near to the factories in which the processes are carried out.) The manufacture of superphosphate makes use of fluorine-containing materials on a large scale. Dr. Roholm raises the question whether the presence of fluorine in superphosphates may not sometimes have a detrimental effect upon the plant life which they are intended to nourish. In the steel and metal-smelting industries fluorspar (CaF_2) is used extensively as a flux; in this case silica tetrafluoride is discharged into the air. Some of the clays used in brick-making contain fluorides, which may be discharged in the kiln smoke. Certain zinc ores contain fluorides, as also do some of the materials used in glass, enamel, and certain chemical industries. It will be realized, therefore, that the potential risk is a real one in this country. If we have in fact escaped from the effects of fluorine poisoning it is probably due to the circumstance that it is, in general, unusual for our industries to be crowded into small and compact districts. It is possible, however, that cases are occurring which have not been diagnosed.

In a search for the evidence of chronic fluorosis the following main points should be given special attention. Dr. Roholm considers (p. 297) that attention may be directed in the first instance to the plant life around the factory. The affected plants are small and show grey or brown spots on their leaves or edges; the leaves fall early and the plants may have deformed fruits. The animal life of the area should then be studied. The symptoms in animals are described with a wealth of detail on pages 38 to 45 and pages 60 to 102. It will be enough to remark here that the symptoms and signs of fluoride poisoning in animals and in man appear to be remarkably similar. In human beings various manifestations of fluoride poisoning may occur. The types of morbid change which are observed depend upon the length of the period of absorption, the age of the patient, and the channel by which absorption takes place.

Dr. Roholm states that chronic fluorine intoxication presents itself in the form of three clinical units: the tooth anomaly, the osteosclerosis, and the osteomalacic condition accompanied by general symptoms. (1) In man the tooth disease is known as "mottled teeth . . . the dental clinical appearance of which appears to be characteristic"—chalky opaque pigmented enamel, and, in more severe degrees, low resistance of enamel and abnormalities of size and shape. The general health is not affected. (2) The osteosclerotic form of the disease is described for the first time in this monograph. Changes which can be studied radiologically are observed in the pelvis and lumbar region and show "uniform density of bone tissue," and especially "calcification in the ligaments"—no destruction of bone occurs and the general health of the patient is little affected. (3) The "osteomalacic" form of fluoride poisoning is similar to fluoride poisoning which has been observed again and again in many countries amongst herbivora. The bones are "reduced in strength," and exostoses, bone atrophy, and defective calcification occur. In typical cases these changes are accompanied by a progressive cachexia.

While it cannot be said that the author's work has finally established the claim of "fluoride poisoning" to be the sole cause of these interesting types of illness, he has presented enough evidence of a very substantial kind to justify further inquiry, and in particular to justify a careful search being made in this country for possible cases of chronic fluoride poisoning.

MENTAL DEFICIENCY

A Text-Book of Mental Deficiency (Amentia). By A. F. Tredgold, M.D., F.R.C.P., F.R.S.E. Sixth edition. (Pp. 556; 34 plates. 25s.). London: Baillière, Tindall and Cox. 1937.

That Dr. Tredgold's textbook should now be in its sixth edition is not to be wondered at. Its virtues, even its idiosyncrasies, have long been known: each successive edition enhances the former and modifies the latter. In its latest revised form it has become more than ever indispensable for all medical officers or practitioners who are concerned with the diagnosis and certification of defectives under the various Acts of Parliament, as well as of great value even to those specialists who undertake the care or supervision of such patients. Each year the literature of the subject grows. From its medical, biological, and sociological aspects alike it is voluminous. So far as is necessary for the purposes of Dr. Tredgold's book, its author has incorporated the main results of published research and authoritative opinion. It is well to note the particular directions in which this has led to a more than minor or general revision. There are extensive alterations in the chapters on causation, psychology, pathology, secondary amentia, and sociology, and considerable additions to these on the nature of mental deficiency, clinical examination (including mental tests), the law and legal procedure, while there is a helpful new section on the chronological development of the human mind.

In the fullness of its content, in logical and orderly arrangement, and in some features of its general outlook, the work has been definitely improved; and though in places it is not without a tendency to dogmatism on matters of some doubt or acute controversy, this is a feature which is not without excuse in a volume among the primary purposes of which is its use as a textbook for students and practitioners. Its main biological heresy can be either approved or discounted by readers of competent knowledge. It is necessary, indeed, to read the chapter on sociology with extreme care. This is not without a tendency to argue from bad or extreme cases, and to accept at their face value some statistical investigations which either were of a too restricted character or the conclusions from which cannot survive the critical scrutiny of the expert. Though the author's suggestions in the realm of eugenics deserve respect and must always be taken into full consideration, some of his generalizations are a little too facile, and are by no means incontrovertible.

DERMATOLOGY IN CHILDHOOD

Skin Diseases in Children. By George M. Mackee, M.D., and Anthony C. Cipollaro, M.D. (Pp. 345; 153 figures. 24s. net.) London: H. Milford, Oxford University Press. 1937.

Not many dermatologists have produced volumes specially devoted to the subject of skin diseases in children, probably because much the same diseases affect the skin at every decade of life. In fact, the older the patient grows the greater variety of skin affections he appears to be liable to, and dermatologists attached to children's hospitals have been known to complain of the monotony of their clinics. The only dermatoses which are really peculiar to infancy and childhood are congenital affections, of which the various kinds of naevi are the most numerous. Until the volume before us, by Dr. Mackee and Dr. Cipollaro, we do not recollect any other English treatise specially devoted to this section of dermatology since Adamson's very useful little book, which appeared about thirty years ago. The authors of this volume do not share the view of dermato-

logy in childhood above expressed. They are inclined to emphasize the distinctions between the dermatoses of childhood and adult life. At all events they have produced an interesting volume illustrated with good photographs of all the commonest and most important affections of the skin, but there is nothing in it which would not be included in any ordinary textbook of skin diseases. In their preface, which surpasses even the majority of American prefaces as a collection of high-minded and conscientious platitudes, the authors lay much stress upon the highly important question of treatment. The therapeutic directions given in the volume are sound, but they remain commonplace. Perhaps the most useful paragraph consists of the directions for making Pusey's calamine emulsion, which forms a very elegant creamy-pink application for treating mild cases of eczematous dermatitis. Under the heading "Dermatophytosis" the authors describe no fewer than eight varieties of eruption which they consider due to some form of fungus. Many dermatologists would refuse to accept them all as such, but nowadays there is a great tendency to consider every eruption affecting the hands and feet as being caused by fungoid infection. The present authors merely follow the prevailing fashion.

ARMY MEDICAL ADMINISTRATION

Organization, Strategy and Tactics of the Army Medical Services in War. By Lieut.-Colonel T. B. Nicholls, M.B., Ch.B., R.A.M.C. With a foreword by Lieut.-General Sir James A. Hartigan, K.C.B., C.M.G., D.S.O., Director-General, Army Medical Services. (Pp. 372. 10s. 6d.) London: Ballière, Tindall and Cox. 1937.

It is nearly twenty years since the great war ended, and most of the medical men who were serving then have reached an age which prevents their again taking an active part in the field should a national emergency arise. We cannot, therefore, rely on their wide experience gained in France, the Dardanelles, and in Mesopotamia being available, by personal service, and the younger generation of doctors, should they be called upon to serve, will have to depend for their knowledge on what they can learn from books, tactical exercises, and such instruction as is offered them. Lieut.-Colonel T. B. Nicholls, R.A.M.C., presents us with a mass of information on almost every aspect of the subject.

Part I deals with general organization and administration, included in which is an appreciation of the medical situation with a description of the method of calculating the number of casualties and the time and transport required to evacuate them from the battlefield. Perusal of these formulae will indicate the magnitude of the accommodation problems which beset the administrative medical officer. Part II, the largest section, describes the constitution and organization of medical units in the field, in each case giving details of siting, construction, capacity, personnel, medical equipment, transport organization, and duties. Strategy and tactics is the heading to Part III. Here the positioning and movement of medical units are discussed with particular reference to varying phases in a campaign and to special topographical situations. The last part is devoted to administrative exercises in which different medical problems are set and in some cases answered.

The book is a complete summary of all the information that it was possible to obtain from war-time records and from the personal experience of the author, who is to be congratulated on the excellent results he has obtained. He has undertaken and completed a task that more than one officer before him, owing to its magnitude, considered but had not the courage to attempt. All books, however good, are open to criticism, and this one is no exception. It is felt that the methods described are not in all cases up to date or sufficiently elastic to meet modern requirements. For example, no mention is made of air transport of wounded, gas and decontamination centres are given scant notice, while arrangements for disinfestation at medical units are entirely omitted, whereas the chapter on ambulance trains is, in our opinion, comparatively and unduly long. We suggest that a chapter on transport of casualties in desert and mountain warfare would have been a useful and instructive addition. As it stands the book deals almost entirely with such medical arrangements as existed in France during the great war and ignores those peculiar to other theatres. There is a dearth of diagrams: for example, the lay-out of a main dressing station, a C.C.S., a gas centre, or the general scheme of evacuation from the firing line to the base. A map, however rough, would have been of greater help in following the tactical movements of the mobile medical units in one of the staff exercises. These are minor points and detract little from the general worth of the publication.

Every R.A.M.C. officer, Regular or Territorial, will find Colonel Nicholls's book an encyclopaedia of knowledge and information concerning the medical services in war, and should be grateful to him for having presented the subject in such a clear and comprehensive manner. At the same time it can never replace the official manuals, and should be looked upon more as an addition to than a substitute for these.

ROSE AND CARLESS

Rose and Carless Manual of Surgery. Edited by Cecil P. G. Wakeley, D.Sc., F.R.C.S., and John B. Hunter, M.C., M.Ch., F.R.C.S. Fifteenth edition. (2 volumes, pp. 1,618; 948 figures, 18 coloured plates. 30s.) London: Baillière, Tindall and Cox. 1937.

The fifteenth edition of "Rose and Carless" appears in two volumes and is dedicated to Lord Lister with the wording used in the original edition of 1898; while above the dedication is a photograph of the bust of Lister which rests in the Royal College of Surgeons of England. In a preface mention is made of the fact that for some unexplained reason the dedication to Lord Lister was omitted from the last two editions. Since the appearance of the last edition (reviewed in these columns on February 10, 1934) the death of Albert Carless has deprived the work of the last of its original authors.

The new edition shows evidence of much revision; new chapters on surgical shock and the sympathetic nervous system have been added, while the breaking up of the text into two volumes is undoubtedly an advantage, as a single volume work in the same style would be unwieldy. The first eight chapters, which deal with surgical pathology and bacteriology and are contributed by Dr. Carnegie Dickson, have been practically rewritten, and much new matter is incorporated. Mr. V. E. Negus has revised the section on oto-rhino-laryngology and Mr. Bishop Harman that on ophthalmology, Sir Frank Connor that on tropical surgery and Mr. Eardley Holland and Dr. C. Hadfield those on the surgery of the female genital organs and on anaesthesia respectively. Mr. John Hunter has rewritten and enlarged the chapter on thoracic surgery. Illustrations are many and good, but the semi-diagrammatic figure 651 might be modified to accord with modern embryological views and the thyroglossal tract shown passing ventral to the hyoid bone. In the interests of space, Fig. 533, showing the trans-sphenoidal exposure of pituitary tumours, might disappear from future editions, as being only of historical interest to-day.

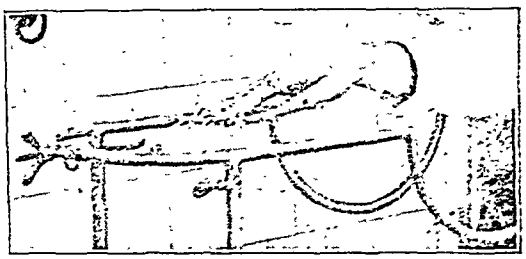
We regret the absence of any reference to the Billroth I type of operation for gastric resection, for this physiological type of procedure has so much to recommend it and is being more widely practised to-day.

This edition of a well-known textbook shows considerable improvement over its predecessors, and in our opinion is the best that has appeared since the last edition by the original authors. We have no hesitation in continuing to recommend this work to students and practitioners.

Notes on Books

Sir THOMAS LEWIS'S masterly survey entitled *Diseases of the Heart* was noticed soon after its appearance in a leading article in these columns on May 6, 1933. We now welcome a second edition (Macmillan and Co., 12s. 6d.). For this the text has been thoroughly revised by the author, and all recent and relevant advances in our knowledge of affections of the heart which it is judged will prove of value to the practitioner have been incorporated.

Disorders of the Blood, by Dr. LIONEL E. H. WHITBY and Dr. C. J. C. BRITTON, was reviewed in these columns on its first appearance in 1935, and the authors were praised for their judgement and skill in compressing a vast subject into small space without deforming it. A second edition has now appeared (J. and A. Churchill, 21s.). During the past two years several notable advances have been made in the science of haematology, and these are reflected in the thirty-five extra pages and seven new illustrations, as well as in some 400 changes in the bibliographies. This edition stresses the value of grouping the anaemias in terms of cell size and haemoglobin concentration, a classification which the authors prefer to one based on the colour index.



In the latter part of 1934 we drew attention to the work of KARL DIEHL and O. F. v. VERSCHUER, who, by studying the tuberculous changes in uniovular and binovular twins, were able to demonstrate that a "specific" hereditary predisposition plays a part in the development of tuberculosis. The same authors have now published a second volume, *Der Erbeinfluss bei der Tuberkulose* (Jena, Gustav Fischer), giving the results of their investigations in greater detail. Moreover, the work now covers 239 pairs of twins (previously they totalled only 127), in 205 of whom tuberculous lesions could be discovered in at least one of the twins; and in addition it has been possible to follow up the original twins for a longer period. The authors maintain that this more extensive investigation confirms in all respects the conclusions in their first monograph.

Dr. JACQUES AUDIAT'S monograph *L'Action des Rayons Ultra-Violet et des Rayons X sur les Nerfs Périphériques* (Masson et Cie, 25 fr.) is a contribution to a subject on which, up to the present, very little research has been done. Although much work has been accomplished in investigating the effects of chemical agents on the function of nerves, study of the influence of physical agents has been limited. The opinion generally held is that *x* rays have little, if any, effect on the function of nerve tissue. As for ultra-violet rays, their penetration is known to be feeble, and that they could affect the peripheral nerves has been thought improbable. By a number of delicately controlled experiments on the isolated sciatic nerves of frogs Dr. Audiat demonstrates that under given conditions (among which variations in temperature are a modifying factor) ultra-violet rays and *x* rays diminish the excitability of the nerve until it is totally suspended. The author contends that the reactions set up in the nerve by irradiation continue after it has ceased, and he has been able to detect chemical alterations in the nerve tissue by spectrum analysis. The effects of ultra-violet and *x*-ray irradiation on the physiological activity of isolated nerve were identical in most respects. The book is an interesting account of meticulously performed experiments which in their present stage are of greater interest to the laboratory worker than the clinician.

Preparations and Appliances

EXTENSION IN CARPAL EXCISIONS

Mr. T. B. MOUAT (Hon. Surgeon, Royal Infirmary, Sheffield) writes: It is now recognized that some form of traction extension is essential in the reduction of a dislocated carpal bone, but it is not so generally appreciated that extension in a Böhler's forearm screw traction frame is equally helpful in operations for excision of a disintegrated carpal semilunar or scaphoid. After the frame has been placed in position, and either local or general anaesthesia induced, extension is applied to the fingers by large plaited cane finger-stalls, which are supplied by Messrs. Down Bros. The fixed extension opens

up the carpal joints, and converts a difficult operation into a comparatively easy one. Before the use of extension I found it was very difficult indeed to remove in one piece a lunate bone softened and deformed by Kienböck's disease, because the bone broke up and peripheral fragments adherent to the ligaments had to be tediously dissected out or removed with a curved dental elevator. With extension it becomes easy to recognize the interspaces and cleanly to excise the diseased bone after division of its ligamentous attachments. There is less discomfort after operation because trauma is reduced to a minimum and the functional result is improved.

WESTERN ELECTRIC 6A AUDIOMETER

The Western Electric Company have recently produced a new instrument known as the 6A audiometer, which seems to be a distinct improvement upon their former models. It is a heterodyne instrument, and has a continuous variable frequency enabling testing to take place at any frequency within a range of about 100 to 10,000 cycles per second—it is practically a pure tone instrument. Bone conduction may be tested both with and without masking. The masking method, which is an improvement, consists of applying the masking tone by air to the ear not being tested. This masking tone is of the same frequency as the tone applied to the ear under test and diminishes in intensity with that of the testing tone. This enables each ear to be tested accurately by bone conduction. Incorporated in the instrument is a microphone, which enables the operator to talk to the patient under test. This acts as a hearing aid, but it is unlikely that it would be necessary to make use of it on many occasions; it is not calibrated and obviously would not be suitable for all types of deafness. The additional cost for the microphone is about £10, and it is doubtful whether this is worth while. The instrument may be obtained without the microphone. While it is possible to obtain a more accurate record of the patient's hearing loss with this instrument, rather more intelligence is required on the part of the patient than is necessary in using the 2B audiometer. The cost of the instrument is 70 guineas, with extras, apart from the microphone, amounting to about another £10.

REGIONAL DISTRIBUTION OF CANCER IN THE OXFORD AREA

BY

G. B. LEYTON, B.A.,

AND

H. G. LEYTON, M.D.

In the course of an analysis of cancer patients who had attended the Ratcliffe Infirmary, Oxford, during the past six years it became obvious that certain streets in the city and some villages in the country around were sending more cases than others. With the view of checking these findings tables of the total deaths were compiled from the registrar's returns covering the whole area, and we are indebted to the medical officers of health for the city and the adjoining districts for permission to use the returns.

General Features

In order to get a true picture of the distribution of deaths it was necessary to place cases in adjoining streets and villages in their relative geographical order, since the division of cases into registration districts breaks the continuity of the grouping. Villages have been classed as adjacent to one of the towns if within three miles.

Points brought out by this rearrangement are:

1. That streets in Oxford adjoining one another get exacerbations in the number of their cancer cases at the same period, and if the cases are marked on a map of the city they show definite grouping.

2. That villages in certain parts of the country around show a similar tendency.

3. That during these exacerbations one or two younger cases often occur.

4. That two or more cases of cancer of the same organ tend to occur at the same time. For instance, in one village there were two cases of cancer of the stomach, two of cancer of the tongue, and two of cancer of the prostate at the same time; and in the market towns this feature is even more pronounced than in the village groups. Cancer of the stomach appears to be very prevalent in these smaller towns, and the cases entered in the death certificates as cancer of the liver may probably be added to these, as primary disease of that organ in cancer is not common.

It is realized of course that in any of the periodic groups shown cases occur which have no relation to any exacerbation; but, judging from the hospital notes, cases of cancer of the alimentary tract in this area most often appear in the death returns within three years, so that the incidence in these cases can be roughly estimated to have taken place three years previously.

While the occurrence of an excessive number of deaths from cancer in any one area is within the realms of chance, it seems necessary to find some other explanation for the widespread nature of this phenomenon over a large district. There are villages not included in these tables where there have not been any cases of cancer, and this is more noticeable in one particular part of a county area. It would be interesting to know whether the above grouping takes place in other parts of the country.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 21 1937

BLACKWATER FEVER

Few problems in tropical medicine are more puzzling, and one may well say more urgent, than that of the causation of blackwater fever, the disease more than any other feared by the European in many parts of the Tropics. Uncomplicated malaria may itself be fatal, dysentery may be a serious cause of sickness and invalidism, typhoid is always a possible contingency, but none of these, and indeed scarcely any other disease that comes to mind, except cholera in the old days in India, has that fatal and dramatic suddenness and fear-inspiring character that blackwater fever has always had to those living in countries where this disease is at all prevalent. The causes of blackwater fever still remain almost as mysterious now as they were thirty years or more ago, when Manson described it in his famous textbook. Long before this, however, the French in West Africa had written largely about the disease. Other nations followed as medical science in their colonies advanced. Koch startled the world by his pronouncement that blackwater fever was the result of quinine poisoning.

Controversy, hypothesis, and a minimum of actual facts or proof have always characterized the writings on this subject, and probably all the advance that has been made now for many years as to knowledge of its essential nature can be summed up by saying that opinion has now become almost unanimous that it is definitely a sequela of long-continued malaria. One might perhaps go further and say that it is also generally recognized to be the result of some change induced in the subject by repeated malaria by which he has been brought very much into the position of the paroxysmal haemoglobinuric—that is, liable to a crisis of intravascular haemolysis when certain exciting causes are brought to bear. But in this case it is clearly not cold that precipitates the attack, and though probably here quinine plays the part of the most usual exciting cause, yet absolute proof or disproof of this is still lacking. We do know that quinine acts in this way in certain quinine-susceptible cases. For this the evidence is overwhelming, but whether the drug is also responsible for precipitating the attack in the usual type of case it is extraordinarily difficult to say, or at least to prove. As to the nature of the changes which bring about the susceptibility, even conjecture fails to give any reasonably helpful theory. Recently some new discoveries regarding changes in the blood in blackwater fever have tended to refocus interest on the vexed question of its causation, and a somewhat remarkable work by Professor J. W. W. Stephens has come at a time perhaps when it is likely to be most needed and useful. This work is a monograph on blackwater fever, and according to the subtitle is "A Historical Survey and Summary of Observations over a Century."[1] Collected in this substantial volume are given "in the original" the numerous facts that during this time have been recorded and the conjectures put forward about this disease. We say, in the original, because this is literally true, the author's method being the unusual one of quoting the cited author's own words so far as possible in appropriate passages. This is supplemented in many cases by a tabular condensation of the cited authors' data bearing on the question under discussion. Consequently, until one has realized what the method is and experienced some of its advantages, perusal of the book is a little alarming. Once, however, the system is grasped the reader will find with great ease, for example, under "urine" every relevant observation made in the literature. As the pages are turned over he can follow, if he wishes, at a glance the evolution of knowledge regarding each feature described. History, geographical distribution, the findings regarding aetiology, relation to malaria and quinine, the blood, the urine, the symptomatology (there are far more symptoms described than one might have thought), treatment, and so on are given seriatim and followed by a number of appendices giving additional details.

The question of the part played by quinine has deeply concerned Professor Stephens. Clearly it is an extremely important matter to know whether or not administration of this drug forms an essential or even a usual precipitating cause. It seemed possible, if records of the disease could be traced to the days before quinine was in use and any relation could be observed between the introduction of quinine treatment and the record of blackwater fever cases, that the issue might be thus decided. Hence there is not only much of interest in the information given by the author regarding the introduction and use of quinine, but also a critical line of research has been followed. Another point is the question of how far back in the literature can undoubted cases of blackwater fever be recognized. Certain references to "black urine" and the cases described with "black urine" by Hippocrates

[1] *Blackwater Fever.* By J. W. W. Stephens, M.D., F.R.S. Liverpool: University Press. London: Hodder and Stoughton. (15s.)

have been taken as indicating records of the disease. But the actual words of Hippocrates and other writers given in the book show how slender is the evidence in this respect. Recently the researches, more especially of Fairley and Bromfield, have added greatly to our knowledge of the biochemistry of blackwater fever. Foy's researches in Greece indicate that country as a field where perhaps the conditions for studying the disease are far more favourable than they have ever been for the investigator in the Tropics.

Blackwater fever, especially in tropical Africa, though its incidence may have diminished in some classes, still remains a most serious bar to colonization by the settler, not only for those of the white race but for Indians, Chinese, "Syrians," and other immigrant races who suffer equally or to an even greater extent. The seriousness of blackwater fever as a colonial problem will, in fact, be no doubt universally granted. Professor Stephens's book should at this stage be both a stimulus to renewed and a guide to past research. In the frontispiece has been reproduced a fine photograph of the great pioneer author in this field, Médecin Général Bérengar Féraud. There is a foreword by Sir Rickard Christophers, whose name is familiar in association with that of the author in many joint contributions on malaria. At the end of the volume is a very complete bibliography.

THE SOCIAL SERVICES

Sir William Beveridge in his recent farewell address as director of the London School of Economics made a plea for the more scientific study of social subjects, and for a recognition of the true place and status of sociology among the sciences. He emphasized that the prime needs were the more extensive observation of facts as the basis of theories rather than argument from philosophic positions, and a real detachment from partisan action rather than judgement on controversial issues. P.E.P. (Political and Economic Planning) is an organization of the greatest value in the desired direction. Its periodical pamphlets are almost invariably adequate, accurate, clear, and unbiased. On the same date as that of Sir William Beveridge's address it published a *Report on the British Social Services*,[1] characterized by all these qualities and containing proposals for the future organization, control, and development of those services. The report gives a general view of the scope and administration of contemporary public social services, demonstrates their growth and magnitude, shows how they relate to one another, and reviews their main underlying principles. Unfortunately in some respects the health services, though properly considered in their relation to the whole, are somewhat less fully dealt with than the rest; but this feature of the report is to be remedied in the early future by the publication of a special report on those services, of the same order of size as the present report, dealing with many relevant matters which have been omitted or summarily treated at the moment. This will be awaited with great interest.

The public social services in this country have developed piecemeal and in somewhat haphazard fashion. There is consequently much confusion and overlapping. Nevertheless two important trends may be noted as having characterized this development: first, the evolution of publicly administered and financed services out of purely voluntary services; and, second, the preference for a number of specific services based on common needs rather than for a comprehensive relief service based on destitution. Further, four motives, distinguishable but changing in relative importance from time to time, are to be found operative in the growth of these services: the charitable motive to mitigate distress; the social motive to establish minimum standards of health education and well-being in the common interest; the democratic motive to reduce inequalities as far as may be; the self-help motive to encourage thrift and foresight. It must be assumed that these several trends and motives will continue to operate, and that any plans for the reorganization and extension of the services must take account of them. In such outlook and planning impersonal environmental services may be left out of consideration, but all those public services which have as their object the enhancement of the personal welfare of individual citizens may well be brought under review with the aim of co-ordinating or unifying them, of remedying their present imperfections, and of filling up any gaps that are left in their operation. Such is the general purpose of the P.E.P. report.

These services may be classified in various ways. In this report they are divided into the constructive community services, the social insurance services, and the social assistance services. The first of these classes includes the education services, the public medical services, the mental health services, the employment services, and the welfare of the blind. The second includes national health insurance, unemployment insurance, contributory pensions, and workmen's compensation. The third includes public assistance, unemployment assistance, and non-contributory old age pensions. Even this enumeration, by itself, discloses inconsistencies of principle and of practice, the bringing

[1] P.E.P., 16, Queen Anne's Gate, S.W.7. (Price 10s. 6d. cloth-bound, 7s. 6d. paper-bound covers; postage 6d. extra.)

together of matters that might well be separated, and the division of services which might well be brought together or amalgamated. While it may be a very convenient classification for the purposes of description, for the purpose of increased efficiency and improved administration it is clearly very imperfect. There are, for example, health and medical services in each of the three divisions, there are services directly connected with unemployment in at least two of them, and the machinery of pensions and of old-age provision is likewise sectionalized. Clearly the need for some degree of unification is already demonstrated, and certain fundamental questions of broad principle are at once raised. To name only two of these, we may well ask: To which of all these provisions is the contributory method best applied? To what extent is it possible and desirable to make the family rather than the individual the unit of consideration?

It is impossible to answer these and other similar questions decisively at the present moment, but, unless confusion is to be worse confounded and uneconomic working to be perpetuated, they require an early, considered, and impartial determination. The P.E.P. report, on the whole, regards the contributory method as valuable and states that it is popular, though it suggests that a flat rate of contribution is not the fairest and should be reconsidered. It looks, too, with greater favour than is common upon some expedient in the nature of family allowances. The repercussions of the social services upon political, economic, and industrial affairs are recognized. There can, indeed, be no attempt to isolate these matters. They should, however, be governed by conscious purpose rather than by unconscious tendency, and there should emerge "a broad strategy of social service development which can take the place of piecemeal improvisations." To this end the report suggests the establishment of "a Social Services Statutory Committee along the lines of the Unemployment Insurance Statutory Committee," with wide and defined functions. This is a valuable suggestion provided that the public social services are first classified on sound lines. Following the lines of policy and thought laid down by the British Medical Association in its consideration of the medical and health services, it would seem most desirable to preserve the large Departments of Education (including the provision of milk and meals while the children are actually assembled in the school), and of Health (unifying all the medical services under the purview of one central department and of a single authority in each local region), and to separate from these all services in the nature of cash payments and material assistance which could be united in one department to which the suggested statutory committee would stand in appropriate relation.

In connexion with any proposals for reorganization, it is important to note two conclusions of the report in relation to the national health insurance service. They are: first, "The administration of the scheme by approved societies is unnecessarily complicated and probably uneconomic. There should be a careful re-examination of the advantages and disadvantages of the present arrangements, and of the case for either eliminating the approved societies or reorganizing them on a regional basis"; and, second, "The local insurance committees perform no functions which could not be more appropriately performed by the local public health authorities, which are usually responsible for all other public medical services in their areas."

RISKS OF EXPLOSION IN ANAESTHESIA

It is unfortunate that many of the anaesthetic agents in use at the present time are inflammable and are therefore liable to explode under certain conditions. While anaesthetic explosions in this country are relatively infrequent they are very alarming for everybody concerned when they do occur. Coste and Chaplin[1] of the London County Council recently carried out some investigations to discover what conditions render these vapours explosive. They found that a mixture of ethyl chloride and air is inflammable when the proportion of ethyl chloride in the mixture lies between 5 and 20 per cent., and in the case of ether vapour and air a concentration of 2 to 8 per cent. can be ignited. If ether vapour is mixed with nitrous oxide the risk of explosion is doubled, as any concentration of ether between 1.5 and 16 per cent. is inflammable; much the same is true of oxygen and ether. It was also found that the vapour produced by bubbling oxygen, with or without nitrous oxide, through ether in a Boyle's machine or Shipway's apparatus produced a very inflammable mixture; even if the gases were passed through the chloroform bottle as well it was still possible to explode the mixed vapours. On the other hand, the risks of explosion in the course of open ether anaesthesia were found to be very slight. Samples of air taken at a distance of two inches from the patient's mouth contained too small a percentage of ether to ignite, even after the anaesthetic had been in progress for one hour and ten ounces of ether had been used. Both ethylene and acetylene have proved explosive when mixed with oxygen for the purposes of anaesthesia, and cyclopropane, too, is a potential source of danger. This is, of course, only one side of the problem. Of even more importance to the anaesthetist is the source of the spark which may explode the anaesthetic mixture. A red-hot cautery or a diathermy electrode is an obvious danger, especially when used in or near the mouth. Less obvious are the risks attached to the use of electric light bulbs on oesophagoscopes or bronchoscopes. If these bulbs are loose or if the in-

[1] *Brit. J. Anaesth.*, 1937, 14, 115.

sulation is faulty a spark may arise, and at least two explosions appear to have been caused in this way. A hot dental needle has also been responsible for an explosion, though the temperature of the metal was below that required to produce red heat. Lastly, there are the sparks produced by static electricity. An anaesthetic explosion due to a discharge of static electricity formed the subject of a paper read by Dr. R. Ironside before the Section of Anaesthetics of the Royal Society of Medicine in March, 1935,[2] and some eighteen months ago the Minister of Health issued a memorandum[3] on the possibility of explosions in operating theatres, with particular reference to static electrical charging, which was considered at length in these columns.[4] In America several writers had already drawn attention to the possibility of the frictional electrification of equipment used in operating theatres.[5] Considerable static voltages were produced there, and regarded as creating a serious risk of anaesthetic explosion, merely by the movement of blankets over metal operating tables.[6] In this country the Medical Research Council, prompted by an Anaesthetics Committee set up jointly with the Royal Society of Medicine, in December, 1935, requested, through the medium of the Department of Scientific and Industrial Research, the assistance of the National Physical Laboratory in investigating the whole question of static electrification as it affected operating theatres.[7] A full account of the completed work is to be given by Dr. E. H. Rayner early in 1938, but meanwhile it is possible to adopt at least two methods for minimizing the risks involved. The rubber wheels of trolleys, etc., often provide insulation sufficient to allow dangerous charges to accumulate. As has been pointed out before, one method of preventing this accumulation is by earthing the metallic parts of the equipment by a light chain trailing on the theatre floor, which, though highly resistant, has usually sufficient conductivity to dissipate any static electrification which the equipment may acquire. Another method which promises to be most valuable, we are informed by the National Physical Laboratory, is the use of electrically conducting rubber for tyres, tubing, breathing bags, etc. Samples of rubber equipment of satisfactory conductivity have been made, and the application of such conducting rubber to anaesthetic and surgical equipment should go far to eliminate the dangers of anaesthetic explosions due to static electrification.

THE MODE OF ACTION OF RADIATIONS ON CELLS

The radiotherapy of malignant disease has made remarkable progress on a mainly empirical basis, but it is becoming increasingly evident that the solution of certain important questions—for example, the selective effect of different wave-length radiations, the optimum dosage rate, the time interval between successive doses, and the duration of a course of treatment—depends upon accurate knowledge of the events which intervene between the irradiation of the cell and the biological result. Such fundamental knowledge is the object of intensive research in several centres both in this country and abroad, and a recent report by Dr. C. M. Scott[1] gives a coherent account of the nature of the biological action of x and γ rays, and suggests the ways in which further progress will be most profitably achieved. Dr. Scott points out that most of the disagreement between different investigators has been due to the absence of a quantitative outlook. The physical measurement of a dose of radiation is difficult, so that physical inaccuracies, combined with the inevitable inaccuracies of biological measurements, account for many disputes over matters of fact. In his own work Dr. Scott has used two types of tissue—the isolated frog's heart and the eggs of *Calliphora erythrocephala*—and by adequate controls and accurate measurements he has been able to show that the primary action of x and γ rays is entirely independent of the metabolic processes of the living cell. Thus the process by which x and γ rays injure living cells is unrelated to the respiratory system of the cell, to its glycolytic function, to its enzyme systems, to its nitrogen metabolism, to the viscosity of its protoplasm, or to its hydrogen-ion concentration. It therefore appears that the action of radiation is primarily exerted on the nucleus of the cell, and thereby on the cell processes which control growth. The conclusion is important, because much has been made of the apparent resemblance between the injuries due to irradiation and those due to other causes, such as temperature changes, oxygen lack, etc. Such agents tend to injure protoplasm generally: doses of radiation of the order of 100,000 r will produce such general non-specific effects, but doses of the order of 1,000 r—that is, of the therapeutic order—have only a specific effect by selectively injuring the nuclei of dividing cells. The action is a graded one, ranging from a completely reversible inhibition of growth to an inhibition that results in the death of the cell. The difference between the sensitivity of dividing cells and that of non-dividing cells is often enormous, and no such difference has been established for any type of injury except that produced by x and γ rays. The demonstration that the action of radiation is specifically upon the cell nucleus and that it is unrelated to other kinds of cell injury, and that, furthermore, it is of a graded character, leads to the conclusion that the "quantum hit" theory is quite untenable. This theory supposes that the survival curves of a number of cells exposed to radiation show the relation between the dose of radiation and the percentage number of cells that have received by chance a sufficient number of quantum hits to produce death. This is the theory adopted by most physicists to explain the varying radiosensitivity of cells. The alternative theory—that the survival curves express the distribution of the variation of the resistance of the individual cells irradiated—is that preferred by most biologists, and may now be said to be established. What is more, variations in radiosensitivity of different types of cells and of tissues at different stages of development are of far greater significance than the variations during the mitotic cycle of any particular type

[1] *Some Quantitative Aspects of the Biological Action of X and γ Rays.* By C. M. Scott. Med. Res. Counc. Spec. Rep., No. 223. H. M. Stationery Office. (1s. 6d.)

of cell. Dr. Scott emphasizes that radiations do not directly stimulate normal activities of the cell. Their primary effect is always an injury. Small doses of irradiation produce genetic effects or analogous changes in somatic cells, larger doses inhibit growth, and still larger doses result in so severe an injury that death of the cell results. As regards the time-intensity factor, he concludes that the biological effect of a given quantity of radiation is less when administered over a long time than when the same quantity is given in a short time, but that as the time is further shortened there comes a point beyond which the time-intensity factor ceases to influence the biological result. The time-intensity factor can be most simply explained in terms of the recovery processes of cells, so that further progress in the technique of radiotherapy depends upon greater knowledge of such processes. Dr. Scott also finds that the influence of the wave-length of a radiation is relatively small, producing biological actions that vary over less than a fivefold range. The general tenor of this report is a great encouragement to the radiotherapist in that a biological approach to the problems of the clinical use of radiations is shown to be of more importance than the physical; at the same time future progress depends upon careful measurement, both physical and biological, whenever any tissue is irradiated.

SPLANCHNIC PAIN

In a recent paper Leriche[1] describes the occurrence of pain on dividing the splanchnic nerves in two patients operated on under spinal anaesthesia extending from the first lumbar segment. Under perfect parietal anaesthesia the splanchnic nerves were exposed below the diaphragm through an incision under the twelfth rib. An attempt to divide with scissors the left greater splanchnic in a vigorous man suffering from thrombo-angiitis was followed immediately by complaint of severe pain in the region of the heart; this lasted until the central end of the partly cut nerve was infiltrated with novocain, when it disappeared at once; section of the lesser splanchnic was not felt. In a second patient suffering from hypertension partial division of the right splanchnic provoked a cry of pain, localized in the right lung. Again infiltration of the central end of the nerve arrested the pain. Leriche supposes first that the appearance in these patients of pain referred to the heart and lung must be attributed to events taking place in these organs. He suggests, therefore, that in man stimulation of the central end of the splanchnic nerve produces reflex vasoconstriction in the heart and lungs, and that such vasoconstriction gives rise to pain; some such reflex, he supposes, may be responsible for the well-known influence of meals on the occurrence of angina pectoris. The facts which Leriche brings forward are not as yet controversial, but it is quite unnecessary to invoke reflex vasoconstriction to explain them; there is no evidence that vasoconstriction in the lung produces pain, and, as Wayne and Graybiel[2] have pointed out, the influence of meals on angina pectoris is probably due not to a reflex from the stomach but to increased cardiac output. It is certain that pain can be evoked from the abdominal viscera under certain circumstances, such as distension, and it is known that such pain is often referred to a part of the body surface not overlying the offending viscus. It is probable that the nerve impulses responsible for visceral pain travel with the sympathetic nerves, including the splanchnic, and it may be suggested that the pain in Leriche's cases was a direct appreciation by the sensorium of the afferent impulses set up in these nerves by mechanical stimulation. Reference of pain to heart and right lung suggests that the afferent fibres in the left nerve came chiefly from the stomach, and in the right nerve from the region of the liver, or diaphragm.

LORD NUFFIELD HONORARY FREEMAN OF THE SOCIETY OF APOTHECARIES

Lord Nuffield's great and generous services to medicine received further recognition this week when on August 17 the honorary freedom of the Society of Apothecaries was bestowed upon him at a full meeting of the Court of Assistants. Introducing to the Court "our distinguished visitor, whom you are about to admit to the honorary freedom of this ancient society of craftsmen," Dr. E. W. Ainley Walker said that Lord Nuffield was especially known to the medical profession by the splendour of his munificent benefactions to medicine and by the magnificence of his noble deeds. In every department of sound and sane humanitarian effort his name held a foremost place. The extent of his generous gifts and immense endowments was almost unprecedented. The greater part of these had been devoted to the alleviation of suffering and the improvement of the health and well-being of the less favoured of his fellow countrymen. The Master of the Society of Apothecaries, Dr. A. P. Gibbons, then presented to Lord Nuffield the certificate of freedom in a casket of cedar wood cased in royal blue morocco leather, bearing the Society's coat of arms in gold. The ceremony was followed by a Court dinner. It is customary at Court dinners that there should be no speeches, but on this special occasion the Master said he would break the custom. In proposing the toast "Our New Honorary Freeman," he said in a brief and gracious speech that Lord Nuffield had conferred enormous benefits on medicine and humanity in general, and had honoured them by accepting the freedom of the Society. In reply, Lord Nuffield said that he would like them to feel how deeply he appreciated the honour bestowed upon him. He would in the future try to continue to do what he had done in the past, and to help medicine and surgery and the teaching that brought about the results that were being achieved to-day. He would do what little he could to alleviate human suffering. Those who had the advantage of good health should help those who were less fortunate.

We print at p. 394 a letter from Sir Frank Colyer asking for gifts of old types of instruments for the extraction of teeth, especially the early nineteenth century types. It will be much appreciated if any reader possessing these will forward them to the Royal College of Surgeons, where they are wanted for the odontological section of the museum.

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

BASAL ANAESTHESIA FOR SHORT OPERATIONS

BY

J. H. T. CHALLIS, M.R.C.S., L.R.C.P.

As this article is intended essentially for those general practitioners desiring to administer basal anaesthetics four main principles have been kept constantly in view. All practical technique will be dealt with in detail so far as possible. Dosage has been selected with the idea of playing for safety. Expensive apparatus and elaborate technique have been avoided. Only those drugs which have been duly tried and found by constant use to be satisfactory to anaesthetists will be described.

Evipan and Pentothal Sodium

Basal anaesthetics of note for short operations can be limited to evipan and pentothal sodium. The first is produced by Bayer's Products Ltd., London, and the second by Abbots Laboratories, Ltd. They are both administered by the intravenous method, and have many properties in common. The advantages of these basal anaesthetics other than as a premedication can be summed up as follows. They provide a most pleasant form of inducing anaesthesia. There is some elimination of post-operative vomiting. By their use irritating inhalants are avoided. There is quick recovery of consciousness.

Patients who are going to be given a basal anaesthetic should be in a nursing institution and under the direct care of the nursing staff for at least twelve hours following anaesthesia. In a great number of cases this is impossible, but every care should be taken that the patients are properly looked after, as in a few isolated instances mental symptoms have occurred after an apparently perfect return to consciousness even as late as some eight or ten hours following administration of the drugs.

Pre-operative Preparation

Though it is not absolutely essential premedication by omnopon 1/3 grain and scopolamine 1/150 grain at least one hour before the induction of anaesthesia is of value, doses naturally being diminished in the case of young people or the old and feeble.

Although many prolonged operations have been performed under these basal anaesthetics it is not considered advisable, except for those with considerable experience, to employ them for surgical procedures lasting more than from ten to fifteen minutes. As the time of anaesthesia is limited it is desirable that all pre-operative preparations should be carried out before the induction, probably the most important of these being the placing of the patient, if possible, in the necessary position for a particular operation. Once the needle has been introduced into the vein gross movements of the patient, such as turning him into the left lateral position, tend to displace the needle and necessitate reintroduction. In the lithotomy position the patient can be placed well down the table, though the actual elevation of the legs need not be attempted until anaesthesia has been obtained.

It is as well to mention that these barbiturates cause a fall of blood pressure, and it is therefore not advisable to administer them other than in the recumbent position; although it must be admitted that this is constantly done with apparently little ill effect, as in dental operations.

Preparation of Evipan and Pentothal Sodium

Evipan is supplied in a glass ampoule holding one gramme of white powder, and with it another ampoule of 10 c.cm. of sterile water. The two are thoroughly mixed some ten minutes before use, and are then drawn up into an ordinary 10 c.cm. Record syringe with an eccentric nozzle, thus making a 10 per cent. solution. Pentothal sodium is also put up in ampoules containing either 0.5 gramme or 1 gramme, and is yellow in colour: 10 or 20 c.cm. ampoules of sterile water are purchased separately. The water and pentothal sodium are mixed together so as to prepare either a 5 per cent. or a 10 per cent. solution. Neither of these preparations should be used if it has been mixed for more than two hours.

Syringes and needles employed for intravenous work can be sterilized either by being kept in spirit or by boiling. The latter tends to be expensive as so many syringes crack. Whichever method is adopted it is well to wash all the parts thoroughly in distilled water before using. The skin should be cleaned with spirit or iodine before introducing the needle. For actually mixing the preparations an old spinal needle is of great advantage, as it is sufficiently long to go to the bottom of the ampoule, thus thoroughly mixing the contents without spilling them, and leaving the intravenous needle ready for use in perfect condition.

Method and Technique of Administration

Before deciding to administer either of these basal anaesthetics it is as well to examine the patient and to ascertain if he or she has suitable veins for an intravenous injection. There is no greater disappointment to the patient or the anaesthetist than failure of this type of anaesthesia if it has once been promised. Any vein that appears to give easy entry will do, with the exception of a varicosed one, in which the drug is likely to stagnate, thus producing slow anaesthesia, possibly thrombosis, or damage to the vein.

The vein selected (usually the median basilic in the antecubital fossa is most convenient), manual pressure is applied or a constricting band is placed above the site chosen and sufficient pressure exerted to engorge the vein but not to impede the arterial pulse. This is best done by an assistant constricting the arm above and steadying the patient's wrist below. Any tourniquet that cannot be immediately and smoothly released tends to change the position of the intravenous needle and jerk through or out of the venous wall. A sharp needle with a short bevel, about 1½ inches long, size No. 17, is most suitable. Blood is aspirated into the syringe to ascertain whether the needle is in position; when it is, it is most important that the manual pressure or constricting band should be completely released, otherwise it is possible for a large dose of the injection suddenly to be liberated into the blood stream.

Two to three c.cm. are injected in about fifteen seconds, during which time the patient is encouraged to talk or asked to count. Unconsciousness occurs in about fifteen to thirty seconds. A safety pause in the administration is very advisable at this point to ensure that the patient's

condition is within the normal limits of safety. The time taken to inject the next 3 or 4 c.cm. should be approximately thirty seconds, when another safety pause is essential, after which, if it is deemed necessary, the remainder of the syringeful can be injected.

The main points to watch during the whole time of administration are that (1) the patient has a perfect airway and the jaw is well supported; (2) depression of respiration is not allowed to progress too far; (3) the pulse rate should not rise. Should it be thought necessary to prolong the anaesthesia the syringe can at this stage be refilled in preparation for further injections. If anaesthesia is being used for operations in the mouth it is essential that a prop or gag should be introduced before the onset of anaesthesia, as spasm of the jaw may make the operation difficult if not impossible.

The signs of the onset of anaesthesia are slurring speech and depressed respiration; nystagmus; sometimes sighing or yawning; pupils small and turned down, later becoming central; early loss of corneal reflex. During the induction stage tremors or movements may occur with evipan, but rarely with pentothal sodium.

Indications and Contraindications

Basal intravenous anaesthesia may be used as a premedication to put patients completely to sleep in their beds; for short surgical procedures such as dental extractions, insertion of radium, dilatation and curettage, eye operations, painful dressings, etc; to counteract ether convulsions; for childbirth, especially in mental patients—when 2 c.cm. of 10 per cent. pentothal sodium should be given at the onset of strong pains, 2 c.cm. more after one minute, and then 1 c.cm. as required.

The following are contraindications to basal intravenous anaesthesia.

1. Patients who have any respiratory obstruction or dyspnoea. Operations on the air passages.

2. Liver diseases or any impairment of its function. Kidney disease is not considered a contraindication, but should this be advanced it would be well to avoid this type of anaesthetic.

3. In children, in whom small air passages make it difficult to maintain a perfect airway. It is also difficult to give intravenous injections to a child.

4. Hypotension, hypertension, and myocarditis are poor anaesthetic risks generally.

5. Toxic patients, who take a long while to eliminate the drug.

Comparison of Evipan and Pentothal Sodium

Those about to embark on intravenous anaesthesia would be advised to start with evipan, for the following reasons. Should the drug be injected into the tissues outside the vein no local reaction will occur with evipan, although there will be a failure of anaesthesia; with 10 per cent. pentothal sodium acute local inflammation and even ulceration may take place, especially if not recognized and treated immediately with hot packs for five or six hours. Even with a 5 per cent. solution local reaction may occur and should be carefully treated. Respiratory depression is less marked with evipan. The depth of anaesthesia is usually not so great with evipan. Some patients complain of a smell or taste of sulphur after anaesthesia with pentothal.

The advantages of pentothal sodium are as follows. The induction is smoother and there is less likelihood of twitching and jactitation, which do occasionally occur with evipan, especially if it is mixed immediately before use. The fall of blood pressure is less marked. The depth of anaesthesia is more profound. Therefore, if a 10 per cent. solution is used its rate of injection should be much slower than as described in a previous paragraph, and a third or even fourth safety pause introduced during the injection of the 10 c.cm. Premedication is not essential, but, if given, much smaller doses of pentothal are required. Post-operative vomiting when pentothal has been administered alone is practically unknown.

Antidotes

The main complications are respiratory depression or respiratory embarrassment caused by lack of a perfect airway. The obvious remedy is to maintain so far as possible a perfect airway and to administer respiratory stimulants. By far the most efficient is carbon dioxide, 5 per cent. or 7½ per cent. in oxygen, administered under slight pressure in a closed bag. Lobeline 3/20 grain may be injected subcutaneously, or, in bad cases, intravenously. Coramine, 5 c.cm. hypodermically or 3 c.cm. intravenously, is of the greatest value in cases of collapse.

In the event of a patient becoming restless and more or less uncontrollable following this type of anaesthesia the intravenous injection of omnopon 1/3 grain will be found immediately to have the desired quietening effect.

The annual congress of the Chartered Society of Massage and Medical Gymnastics will be held at the London School of Economics, Houghton Street, Aldwych, W.C., from Monday, September 20, to Friday, September 24. The meetings are open to all medical practitioners, and lectures will be given as follows: September 20, 10.30 a.m., Professor G. R. Girdlestone, "Treatment of Scoliosis in an Orthopaedic Hospital"; 12 noon, Miss Maud Forrester-Brown, M.S., M.D., "The Place of Physiotherapy in the Treatment of Injuries"; 2.30 p.m., Mr. K. O. Parsons, "Treatment by Manipulation." September 21, 10 a.m., Mr. A. Lawrence Abel, "Surgery of the Sympathetic Nervous System"; 11.30 a.m., Mr. J. G. Yates Bell and Dr. F. S. Cooksey, "Faradism and Pelvic Floor Exercises for Urinary Incontinence"; 2.30 p.m., Dr. A. T. Todd, "A System of Treatment for Chronic Rheumatism"; 8.30 p.m., Dr. Noel Harris, "Hysteria." September 22, 10 a.m., Dr. Doris M. Odlum, "Psychological Factors in Physical Disease"; 11.30 a.m., Mr. H. J. Seddon, "The Application of Occupational Therapy to Orthopaedic Conditions"; 2.30 p.m., Dr. W. S. C. Copeman, "Chronic Rheumatism." September 23, 10 a.m., Mr. A. E. Porritt, "Ruptures—Ancient and Modern"; 11.30 a.m., Lady Barrett, "Effect on Maternity of Physical Activities during Adolescence"; 2.30 p.m., Mr. A. Wilfrid Adams, "Orthopaedic and Other Operations under Spinal Anaesthesia"; 6 p.m., Miss E. R. Clarke, "Development of the Movement to Improve the Physical Fitness of the Nation"; 8.30 p.m., Dr. J. Kalmanson, "Indications for Short-wave Therapy." September 24, 10 a.m., Mr. E. R. Desoutter, "Artificial Limbs"; 11.30 a.m., Dr. Clement Nicory, "Importance of the Physical Therapeutist in Preventive Medicine"; 2.30 p.m., Dr. R. L. Kerr, "Remedial Exercises in the Treatment of Abnormalities of Binocular Vision and Asthenopia"; 6 p.m., Miss Ann Driver, "Music and Movement"; 8.30 p.m., Founders' Lecture by Mr. H. A. T. Fairbank, "Some Unusual Causes of Backache." The annual general meeting will be held on September 20, at 5.30 p.m., and will be followed, at 8 p.m., by a debate and discussion. The annual dinner will be held at the Café Royal, Regent Street, W., on September 22, at 7.30 p.m. Arrangements have been made for visits to be paid to various hospitals and institutions during the congress, and practical classes will be held daily. Applications for tickets and for all information regarding the exhibition and annual dinner should be made to the secretary, Chartered Society of Massage and Medical Gymnastics, Tavistock House North, Tavistock Square, W.C.1.

INTERNATIONAL HEALTH

SURVEY OF THE PERMANENT COMMITTEE

The report of the medical director of the International Health Office of the proceedings at the session of the Permanent Committee in May, 1937, has now been issued.[1] Dr. M. T. Morgan of the Ministry of Health was the delegate of the United Kingdom. It was reported that Turkey, Greece, and Czechoslovakia have further ratified the Convention for Mutual Protection against dengue fever, signed at Athens in 1934. An international arrangement to overcome difficulties connected with the transportation of corpses has been signed by the plenipotentiaries of nine countries. With regard to the Brussels Agreement, 1924, for the treatment of sailors suffering from venereal diseases, the adhesion of Germany was noted, as was the receipt of further replies favourable to the acceptance of the Committee's recommendations on the organization of the treatment to be offered. Communications from several countries and observations made in Great Britain and Australia concerning the deratization of ships confirm the fact that the number of ships with a large rodent population on board has strikingly diminished. Other interesting problems which were discussed arose in connexion with the Mecca Pilgrimage and the danger of the spread of yellow fever by persons using international air lines.

Plague

Papers on this subject included a general survey of plague in French Colonies (West Africa, Madagascar, and Indo-China) in 1935 and 1936. In Indo-China there have been few cases in recent years, but the disease persists in three restricted foci where it assumes a seasonal character, the greater number of cases occurring during the hot weather. Most of the cases are sporadic, and there is no apparent connexion between them and murine plague; the proportion of primary pneumonic plague cases is 10 per cent. In Madagascar plague has been gradually extending, particularly towards the south, ever since its introduction in 1921. In 1935 and 1936 the proportion of pneumonic cases was 28 and 27 per cent. respectively. This form of the disease is present all the year round, but especially in the cold season. The other forms are most common in the hot weather, corresponding with the prevalence of *Xenopsylla cheopis* and the existence of murine epizootics. Although thousands of rats were examined (75,339 in six years) few plague-infected ones were found.

For anti-plague vaccination in French West Africa various killed vaccines are widely used; they do not seem inefficacious, but are not of great service for plague prophylaxis. In Madagascar 710,852 persons out of a million inhabitants in the plague zones have been vaccinated with Girard and Robie's living avirulent virus. The results were unfavourably influenced by the fact that the experiment coincided with a violent outbreak, and the vaccination could not be carried out in all districts before the epidemic reached them. In spite of this the approximate number of 2,000 cases for 1936 compares well with the average of 3,500 for preceding years. In the best vaccinated districts (77 per cent. of the population) the morbidity rate was 0.59 per 1,000, as against 3.6 in the control districts.

Cholera

Work has been done in India, under the direction of the Consultative Committee for Cholera of the Indian Research Fund Association, to determine if possible the true characteristics of cholera vibrios. Agglutinating sera of pure type O were used, obtained by injecting into a rabbit heated dried antigens, furnished by Bruce White and Gardner. The strains employed were the original type Inaba and the type called "variant" of Ogawa, representatives of Group I of the classification of Gardner and Venkatraman. This vibrio possesses the fermentative properties for sugars which characterize Type I of Heiberg: fermentation of mannose and of saccharose, but no fermentation of arabinose. Its reaction to cholera red is positive, and to the Voges-Proskauer reaction modified by the addition of naphthol-A negative. It does not haemolyse goat's blood. The two Japanese strains "Inaba" and "Ogawa" show all these biochemical characters, but from a serological point of view they have a distinct individuality. Thus for diagnosis two sera prepared respectively from these two strains, or more generally a bivalent serum, must be used.

Colonel Taylor's report tends to show that vibrios not agglutinable by Type O serum which have been isolated from clinical cases of cholera are not true pathogens; the true cholera vibrio may have escaped discovery, and the non-agglutinable vibrio which had been isolated may belong to a type which is perhaps present in the intestine of a fraction of the healthy population. Many of the strains which are not agglutinable by O type serum, and which are not isolated from clinical cases of cholera, of show H agglutination. However, some vibrios isolated in the recent researches from clinical cases of cholera, of which some gave and others did not give typical biochemical reactions, showed H agglutination only. It seems, then, that it is not yet possible to use O type sera exclusively for the diagnosis of pathogenic cholera vibrios.

Yellow Fever

Continued researches in South America by the yellow fever services of Brazil and Colombia, in co-operation with the Rockefeller Foundation, have confirmed the existence of the so-called "jungle" yellow fever in rural areas in which there are very few inhabitants and no *Aedes aegypti*. The problem lies in discovering other possible hosts than man and other blood-sucking vectors than the Aedes.

In Great Britain vaccination against yellow fever has been performed with a pantropic virus attenuated by tissue culture without the addition of immune serum. Observations made on sixty-five cases would seem to justify the use of the virus in this manner. Repeated passage through rhesus monkeys does not seem to increase virulence, consequently a return to a virulent form need not be feared, nor does the virus appear likely to become neurotropic. Experimental infection of mosquitos by virus circulating in the blood of humans or monkeys has not yet been effected.

Small-pox

As a result of the extension of vaccination and revaccination against small-pox, this disease has practically disappeared from the U.S.S.R. There were 385 cases in 1936, and none in the first quarter of 1937; 47,461,305 vaccinations or revaccinations were carried out in 1935, and 39,869,718 in 1936. The usefulness of vaccination has been confirmed by experience in the war in Ethiopia. While there were numerous cases of small-pox among the Abyssinians, there was only one case in the Italian Expeditionary Force, all the members of which had been revaccinated. In Italy it is proposed to give vaccination against small-pox and the first injection of diphtheria anatoxin simultaneously; the second injection of anatoxin will be given ten days later; the age prescribed for vaccination will be the second year, a time preferable for diphtheria immunization, which will be made compulsory.

Other Infectious Diseases

In New Zealand an epidemic of poliomyelitis broke out at the beginning of December, 1936; by the end of March, 1937, 341 cases had been notified. In the first three months of the epidemic the percentage of non-paralytic cases was 42.9. It was considered necessary to close all the schools in New Zealand.

[1] Paris: Office International d'Hygiène Publique, 195, Boulevard St. Germain.

In the United States small, violent, and localized epidemics of cerebrospinal meningitis appear about every seven years. The most recent (1935–7) seems to be on the decline. Some are produced by a single type of meningococcus, others by several types; type I-III (type A in France) is the most frequent during the epidemic periods.

Epidemics of encephalitis, similar to the so-called St. Louis encephalitis, which has been prevalent in the United States, occur in Japan more or less every year in certain prefectures. The virus has been transmitted to monkeys by inoculation of the cerebral matter of dead persons, and then to the mouse, which is the most receptive laboratory animal; it is present in the brain of patients from the fourth to the tenth day of illness, and cannot be shown after the tenth day.

The increased incidence of scarlet fever in Rumania in recent years led to a campaign of inoculation by streptococcal anatoxin in 1934. Four injections were given at intervals of two and three weeks; in Bucarest 25,000 children were inoculated. Those that subsequently contracted scarlet fever were compared in two groups, one of 229 inoculated and the other of 776 non-inoculated children. Among the former there were more mild cases, fewer complications, and fewer cases of ulcero-necrotic angina (3.1 instead of 13.8 per cent.) and malignant scarlet fever (0.44 instead of 2.2 per cent.). The total mortality amounted to 0.44 per cent. among inoculated and 7.2 per cent. among non-inoculated children.

Tularemia

Tularemia has made its appearance in Central Europe (Lower Austria, Moravia, and Slovakia) and in Turkey in Europe. The first case in Lower Austria was notified in 1925, and the second in September, 1936, followed by about a hundred cases in the adjoining district on the Moravian frontier. Then the disease appeared in Southern Moravia at the end of October, 1936. Thirty to forty-five days before the first human cases a great mortality was reported among field voles and then among hares. From Moravia the disease spread to the southern part of Slovakia. In all, up to April 15 there were 391 cases in Czechoslovakia, of which 277 occurred in Moravia, 110 in Slovakia, and 4 at Prague (caused by hares coming from infected districts). The forms were glandular and ulcero-glandular, and occasionally typhoidal; there were also oculo-glandular forms, with slight ocular lesions. Contact with hares was proved in 90 per cent. of cases; the others were caused by contact with wild rabbits and mice. The place of entry was sometimes a small skin wound, but in other cases the place of the initial lesion seemed to be the mouth or throat, and the illness began with angina accompanied by extensive oedema.

In Turkey the first cases were discovered in June, 1936, among soldiers in the garrison of Luleburgaz in Thrace, and continued to occur up to the end of September. The forms were generally glandular or oculo-glandular (32 per cent.); none were typhoidal. *Bacterium tularense* was isolated from human cases. The infection would appear to come from wild rabbits. It may have been transmitted by insects in some cases, but investigations which were made on this point—possibly too late—were not conclusive.

D. Ciddio (*Policlinico*, Sez. Chir., May 15, 1937, p. 246) in order to determine the results on the kidney of the removal of the aortico-renal ganglion which forms part of the coeliac plexus, carried out the operation on six dogs under morphine and chloroform anaesthesia. He studied successively the functional changes in the corresponding kidney and also the histological lesions. In the first few days after the operation he found that the kidneys showed a considerable vasodilatation followed by vasoconstriction, and finally at the end of two and a half months a return to the normal condition. He comes to the conclusion that this operation might be indicated in suitable cases.

ENGLAND AND WALES

London Chest Hospital Pathological Laboratories

The report for 1936 of the Pathological Laboratories of the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park—to be known from now on as the London Chest Hospital—contains the usual summary of post-mortem records and of the routine laboratory examinations carried out for the out-patient department and in the in-patients. They totalled no fewer than 10,307. In addition 1,981 examinations were undertaken for various public bodies, consisting mainly of the examination of milk samples, swabs for diphtheria, and histological examinations. The report also contains reprints of four papers published by the staff of the laboratories. Three articles are by Dr. Gloyne. The first describes the morbid histology of pulmonary abscess cavity walls: in one case the cavity was bronchogenic, in the other associated with an interstitial abscess. In the second paper are given the results of an investigation into the relation of congenital heart disease to pulmonary tuberculosis. The 2,735 necropsy records at the hospital between 1889 and 1935 showed twenty-one cases of defects of the heart "which may be presumed to have been congenital." Six of these had tuberculous pulmonary lesions. But such lesions were not present in the six cases of congenital heart disease that were associated with cyanosis. Dr. Gloyne's third paper gives an account of a case of oat-cell carcinoma of the lung occurring in asbestosis. The last paper is by Dr. Shishkin. She concludes from her investigations that there is no evidence that infection of rabbits with virulent bovine tubercle bacilli has any effect on the *p*H of the blood.

Medical Society of London

The first half of the session 1937–8 of the Medical Society of London will open on Monday, October 11, with the annual general meeting at 8 p.m., followed by Mr. J. E. H. Roberts's presidential address on "Sick Nursing—Past, Present, and Future" at 8.30 p.m. On Monday, October 25, at 8.30 p.m., a discussion on treatment by intravenous infusion will be introduced by Dr. George Graham, Mr. G. Gordon-Taylor, and Dr. H. I. Coombes. A discussion on national physical training will be opened by Sir Joseph Barcroft, F.R.S., Lord Burghley, Dr. Adolphe Abrahams, and Mr. A. E. Porritt, on Monday, November 8, at 8.30 p.m. A clinical meeting will be held on Monday, November 22, at 8 p.m. On Monday, December 13, at 8.30 p.m., Mr. H. W. Rodgers, Dr. G. T. Calthrop, and Dr. S. Cochrane Shanks will introduce a discussion on modern methods of investigating gastric diseases. The Lettsomian Lectures, on a survey of the changes and results of treatment of diabetes in the last fifteen years, will be delivered by Dr. George Graham on February 21 and March 2 and 7, 1938, at 9 p.m. Sir Henry Gauvain will deliver the annual oration on "Planning a Hospital" on Monday, May 9.

Cancer Research in Yorkshire

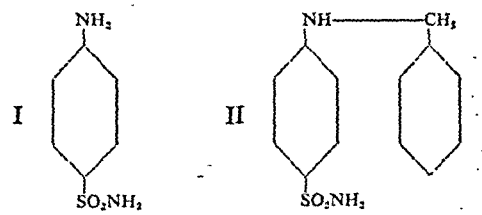
The annual report for 1936–7 of the Yorkshire Council of the British Empire Cancer Campaign records a benefaction of £25,000, the gift of one of the honorary treasurers, Sir Algernon Firth. The report includes accounts of the progress of cancer research in the Universities of Leeds and Sheffield. In a study of the problem of industrial cancer of the bladder attempts were made to demonstrate the presence of carcinogenic constituents in the urine of workmen employed in the aniline dye industry. Large quantities of urine were extracted and tested for carcino-

genic activity by painting the skin of mice. The results of these tests, however, were completely negative. In the course of experiments on the action of different chemical substances on cancerous growths, with a view to the discovery of some substance specifically destructive to the growth while not unduly toxic to the body, the action of iodine on Rous sarcoma was investigated. The filterable agent was found to be very susceptible to minute quantities of iodine, a dilution of 1 in 5,000 always destroying the power of carcinogenesis when added to a cell-free filtrate. With a concentration of not less than 1 in 750 the filterable agent in sarcomatous cells was killed. The action of iodine thus appeared to be superior to that of potassium permanganate, which had been investigated in the previous year, a concentration of 1 in 200 of this salt being necessary to destroy the filterable active substance. In a further series of experiments, however, the effects of intravenous injection of iodine on fowls bearing Rous sarcomas were disappointing.

SCOTLAND

Mental Hospitals' Pathological Scheme

The annual report for 1936 of the Scottish Mental Hospitals Pathological Board records a marked increase in the amount of material examined. The report refers with regret to the resignation of the Board's pathologist, Dr. J. A. Biggart, who has been appointed to the Chair of Pathology at Queen's University, Belfast. It is stated that Dr. Biggart was responsible both for the organization of the work of the laboratory and for the formation of a valuable collection of photographs, specimens, and slides, in addition to routine examinations and original research. His successor is Dr. A. C. P. Campbell. In order to foster relations between clinical workers and the laboratory the Board has instituted quarterly demonstrations on the pathological aspects of mental disease for the medical officers of contributing hospitals. Although the possibility of some form of itinerant laboratory, or even the eventual provision of several laboratories in the asylums themselves, is envisaged in the future, it is considered that the present laboratory in the Edinburgh Royal Infirmary meets satisfactorily the needs of the moment. Under the existing arrangement it is in close touch with the general pathological laboratories of the University and the Infirmary, and also with other research laboratories, while its contacts with the asylums are not impaired.



Scottish Health Education Campaign

A conference of representatives of Scottish local authorities was held in Edinburgh on July 29 at which Mr. Scrymgeour Wedderburn, Parliamentary Under-Secretary of State, outlined the proposals for a health education campaign in Scotland during the coming autumn and winter. He explained that the Prime Minister was to inaugurate a National Campaign at a conference to be held in London on September 30, and it was hoped that the Scottish local authorities would be prepared to give their full co-operation. The plan of the campaign to be followed in England was to enlist at the outset the public interest in the health services generally, and thereafter to concentrate month by month on giving publicity to the various individual services. It was proposed, however, that the campaign in Scotland should take rather a different line and aim not only at urging the fuller use of the existing services but also at encouraging the maximum development of those services within the framework of existing legislation. During the autumn months full publicity would be given to the Scottish health services, and for this purpose the Department of Health for Scotland was prepared to provide local authorities with publicity material. Following this initial campaign there would be a preparatory stage during the winter and spring leading up to a further intensive effort in the summer of 1938 associated with the Empire Exhibition in Glasgow. There would be close association with the Physical Training and Keep Fit Movement in Scotland. The campaign would obviously depend very largely for its success upon the efforts of local authorities in carrying out local propaganda work.

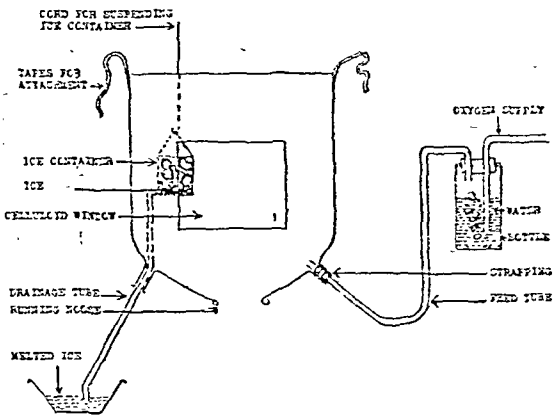
Correspondence

Nomenclature of Sulphanilamides

SIR,—In a letter from Dr. Alfred Model (*Journal*, August 7, p. 295) there appears to be some confusion between *p*-aminobenzenesulphonamide and *p*-benzylaminobenzenesulphonamide. The former drug is the amide of sulphanilic acid (I), and the term "sulfanilamide" has been adopted for it by the Council for New and Non-official Remedies of the American Medical Association. It is distributed in this country under several proprietary names, such as prontosil album (Bayer), sulphonamide-P (Burroughs Wellcome and Co. and British Drug Houses), streptocide (Evans Sons Lescher and Webb). The latter drug, *p*-benzylaminobenzenesulphonamide (II), is distributed in this country only by Pharmaceutical Specialities (May and Baker) Ltd., under the proprietary name of proseptasine.

These two substances differ considerably in chemical, physical, and pharmacological properties (Halpern, B. N., and Mayer, R. L., *Presse méd.*, 1937, **45**, 747; Whitby, L. E. H., *Lancet*, 1937, **1**, 1517), and it is therefore of the greatest importance to avoid confusion between them. Further, it is probable that more members of this group will be introduced into medical practice, so that accuracy in nomenclature is essential. For this reason I suggest that we should follow the example of Dr. A. T. Fuller (*Lancet*, 1937, **1**, 194), and of the Americans, and use the term *sulphanilamide* for any brand of *p*-aminobenzenesulphonamide, and the term *benzylsulphanilamide* for any brand of *p*-benzylaminobenzenesulphonamide, since these names are reasonably convenient and are chemically specific.

The case of agranulocytosis recorded by Dr. Model is, I believe, the first to be associated with benzylsulphanilamide; some half-dozen have been associated with sulphanilamide, and at least one (Borst, J. G. G., *Lancet*, 1937, **1**, 1519) with the original (insoluble) red prontosil.—I am, etc.,



G. DISCOMBE.

Aug. 10.

"Home-made" Oxygen Tent

SIR,—It was with great interest that I read in the *Journal* of April 17 (p. 812) a description of the St. George's Hospital oxygen tent. I attach a photograph of an oxygen tent which was constructed by the sailmaker on board and used with great success in H.M.S. *Shropshire* for a case of myocardial degeneration with con-

stive heart failure. The material used was jaconette, lightweight and waterproof material which is almost ansparent. The tent was constructed in the shape of square funnel, the bottom being fitted round the atient's neck by means of a running noose and the p left open and attached to the cot above. A cleared -ray film was stitched to the front as a window. The xygen was led through a rough flowmeter and was not ed. It entered the bottom of the tent and the tube was ecured to the jaconette by means of surgical strapping. n irrigation can full of ice was, however, suspended side the tent with a rubber tube to lead the melted e away.

The whole thing took about an hour to make. Any housewife worth her salt could make a similar one in as short a time. Its therapeutic efficiency was manifest. On April 7, for instance, an impending Stokes-Adams fit was staved off by its use. The patient was extremely cyanosed, with a completely irregular pulse which had slowed from 100 a minute to 40, and was complaining of acute precordial pain. He was very dyspnoeic, respirations being 36 a minute. There was twitching of the muscles of the face and arms. Before the onset of the slow pulse gallop rhythm had been present, with a well-marked mid-diastolic sound, and pulsus alternans had been felt at the wrist. He was placed in the tent at 2.30 on the afternoon of April 7, and half an hour later the cardiac pain had completely disappeared. At 6 p.m. the patient was a good pink colour, with a pulse of 100, strong and regular, and no bruit de galop present. Respirations were 20, and he was sitting in the tent reading a book. He was kept on board twelve days altogether, and for a large part of the time the tent was in use. He was perfectly happy inside it, the atmosphere always kept cool and fresh, and the celluloid window never misted over. He used to study his face with a small mirror and watch the colour gradually change from blue to pink on being put into the tent after a meal. When he was finally landed at Gibraltar oxygen was no longer necessary, and he could actually lie flat on his back without dyspnoea. The tent was light in weight and the material let so much light through that its use was never oppressive. It was found that it was important to keep the ice can replenished.—I am, etc.,

A. J. GLAZEBROOK,
Surgeon Lieutenant, R.N.

H.M.S. *Tedworth*, July 20.

Elongation and Dilatation of the Colon

SIR,—Professor J. R. Learmonth's conclusions on the above condition of the colon in children (*Journal*, July 24, p. 154) support the views I have formed from radiological observations on adults. The digestive tube possesses three main functions—secretion, absorption, and motility. Only the last of these interests the radiologist, with, in addition, a subsidiary function of storage. The search for organic lesions has induced radiologists to devote time to the study of anatomical appearances, and rather to ignore functional activity, because the latter is more difficult to assess.

Muscle, voluntary and involuntary, possesses two properties, tone and contractility. In the digestive tract contractility is recognized by various types of peristaltic action, and it is also well known, though not always appreciated, that peristalsis exhibits wide variations in health. For this reason its significance in pathological processes is difficult to assess, and it is often ignored therefore by the radiologist. Tone, the other property of muscle, is responsible for striking variations in the width and length of the alimentary tube in healthy individuals. More frequently than in the case of peristalsis have these normal variations been misunderstood by the radiologist. Such mistakes were largely responsible for the useless gastropexies and colopexies of former days, and to-day are responsible for the stress laid in some quarters on duodenal ileus, which is really a rare disease, though often simulated by the hypotonic duodenum.

Functional disturbances of the colon are common and occupy much of the physician's time, but the radiological evidence of their origin and even their presence is apparently trivial and very difficult to identify with certainty. All too often physiological variations are confused with some pathological process, because the variations are surprisingly wide in healthy persons. Too often, also, has the radiologist himself relied upon the clinical evidence for help in interpretation, and has converted a physiological variation into a pathological process. The "would-be" faddist physician and surgeon have often found support for some attractive theory from these unreliable *x*-ray reports.

Unlike Sir Arthur Hurst, whom Professor Learmonth quotes, I think a barium enema gives a good estimate of bowel tone rather than of mere distensibility when certain conditions are complied with. It depends on how the enema is administered: let a thinner suspension of barium be used and allowed to flow through a tube without any obstruction in its lumen at a constant pressure until an evacuation is threatened. If the sphincter ani possesses reasonably good tone and the patient's mentality is reasonably normal and there is no acute inflammatory condition within the abdomen, especially in the peritoneum, then the diameter of the colon forms a reasonably sound index of the colonic tone.—I am, etc.,

JOHN R. WYLIE.

London, W.1, Aug. 12.

When to Operate in Appendicitis

SIR,—May I reply to two letters which have appeared in the *Journal* in connexion with operation in acute appendicitis: one was by Mr. R. Rutherford (July 31, p. 244), and the other by Mr. R. S. Lawson (August 7, p. 294).

Mr. Rutherford suggests that the family doctor can carry out expectant treatment in the patient's home. This treatment requires nursing in a high Fowler's position, which necessitates the importation of a special bed, and constant charting of the pulse and temperature, which implies day and night nursing. I agree that in some homes these facilities might be provided, and possibly the usual domestic noises, including the telephone, which are so irritating to a sick person, might be stilled. But even if the patient can be nursed under the best conditions there still remains the 10 per cent. risk that expectant treatment may fail. An operation then becomes an urgent necessity, and either the patient must be transported to a hospital or nursing home when he should be enjoying absolute rest, or he must be subjected to an abdominal operation in an improvised theatre. An abscess can certainly be opened within "four walls and a roof," even if lighting facilities are rather poor, but most surgeons would prefer a recognized theatre in which to remove a possibly difficult appendix.

Mr. Lawson quotes a case in which a patient ignored "emphatic instructions" to return for appendicectomy after the successful drainage of an abscess. As a reminder to the patient many surgeons arrange for a card to be given him on which is printed the date on which he should return to hospital, with instructions that the card be placed in a prominent position in his home. Responsible relations as well as the patient are frankly warned of the risks of a subsequent attack. If the patient fails to return on the appointed date a further reminder is sent from the hospital. Occasionally the patient may wish to postpone the operation for a short time on account of occupational or domestic conditions, and in some cases a compromise is arranged, but it is very exceptional for warnings and reminders to be completely ignored. I know of no method of divining whether any given patient will fail to return for appendicectomy after successful expectant treatment, but if this argument is considered from the opposite angle surely Mr. Lawson would not submit innumerable tractable patients to an increased risk for the sake of the odd patient who might disobey emphatic instructions.—I am, etc.,

London, W.1, Aug. 10 R. J. MCNEILL LOVE.

Nutrition in Pregnancy

SIR,—I have read with much interest the reports of the papers on nutrition in pregnancy read at the Annual Meeting of the British Medical Association in Belfast and published in the *Journal* of August 7. Especially may I commend Dame Louise McIlroy's excellent paper (p. 258) for its sound, common-sense appreciation of things as they are, and as they should be. Her conclusion is admirable, and applies not only to maternal nutrition but to the wider problem of the nutrition of the whole human race. The significance of the problem of nutrition in its widest aspect has not hitherto been appreciated, and even now it receives far less attention than it merits. Indeed, we have scarce reached the stage of elimination of starvation, far less tackled the question of malnutrition. The evidence is widespread, for unfortunately the rifeness of malnutrition is only exceeded by its far-reaching effects, from vague ill-health to chronic invalidism, from lack of resistance to the common cold to the prevalence of puerperal pyrexia and sepsis. Its burden naturally falls most heavily on the poor, but the rich are by no means immune, for this great social evil, and such it is, springs from three roots. First, economic forces outside the control of the medical profession, but capable of being influenced by the force of enlightened public opinion. Secondly, lack of knowledge both of the rudiments of sound physiological feeding and of the preparation and composition of our food, this ignorance appertaining largely to professional as well as to lay minds. Thirdly, and following from the second cause, a failure to utilize what knowledge we have in the training of both the medical and nursing professions, and a consequent failure in the passing on of our knowledge for general usage.

The remedy is self evident—better education in these matters, first, for the medical student and nurse, secondly, for the lay mind through the professions. The machinery is there already, and may be operated through the Ministry of Health, the child welfare clinics and public health services, the women's institutes, and finally through the medium of the very considerable influence of the ill-used general practitioner. The day must come when the care of the sick as opposed to the care of health becomes only a part of the doctors' work, and not the whole, as it wrongly is at present. Until that day comes we can never hope for the conquest of disease, and I can think of no better start than the regulation of nutrition in pregnancy, that the next generation may at least start life under the best conditions.—I am, etc.,

Erith, Kent, Aug. 13. ERIC TOWNSEND, M.B., Ch.B.

Strangulated Ovary in Children

SIR,—In the *Journal* of August 7 (p. 266) Dr. Fridjohn and Mr. Lee have reported a case of strangulated ovary and hernia in a child aged three months, and have asked if anybody could provide them with details of any case that they have seen. During the last twenty-seven years I have met with four cases of strangulated ovary in infants under three months. They have all presented a very similar clinical picture—namely, that of a large strangulated inguinal hernia which could not be reduced and caused recurring attacks of sickness. I maintain that in a female child under five months the commonest content of an inguinal hernial sac is an ovary or Fallopian tube, and in any case which appears to be strangulated the odds are that this is a twisted ovary.—I am, etc.,

London, W.1, Aug. 11. CECIL P. G. WAKELEY.

Anaesthesia in General Practice

SIR,—Dr. Helen Lukis, in her article in the *Journal* of July 17 (p. 126), throws new light on the problem of the abuse of the voluntary hospitals. Apparently hospital patients have the advantages of nitrous oxide and oxygen, while her private patients are subjected to the admitted hazards and unpleasantness of open chloroform and ether. If this invidious class distinction be widespread, can we blame patients who strive to go to hospitals when they can well afford treatment in a nursing home? Dr. Lukis is at pains to stress the drawbacks of nitrous-oxide-and-oxygen apparatus. Her remarks convince me that she must be referring to apparatus designed many years ago; modern apparatus is admittedly costly in the first instance, but it is reliable. Chromium plate has removed the risk of rusting, rubber tubing is reduced to a minimum and lasts for years, while the impression Dr. Lukis leaves of anaesthetists sitting up late each night feverishly working

to give their apparatus "constant and careful maintenance" is far from being the case.

I should like to endorse what Dr. R. B. P. Lansdown says in his letter published in the *Journal* of July 31 (p. 243) concerning the eminent practicability and safety of avertin in general practice.—I am, etc.,

Hove, Sussex, Aug. 10. REX BINNING.

Prominal in Epilepsy

SIR,—Dr. Eager's comments (*Journal*, August 7, p. 295) on the articles by Drs. Millman and Henderson on the above subject are interesting and, at least to me, confusing. I understood from Dr. Millman's paper that he has proved under conditions of control rigid enough to pass through the eye of the statistical needle that in thirty-nine epileptics the average number of fits was reduced by two-thirds under prominal treatment as compared with luminal treatment. In recommending, as he does in the second paragraph of his letter, the "home-made" product, phenobarbitone soluble, Dr. Eager states that it produces "equally good results." Reference to the *British Pharmacopoeia* shows that the chemical substance contained in phenobarbitone soluble is identical with the sodium salt of luminal (though possibly, as only 95 per cent. purity is demanded, it is less pure). That phenobarbitone soluble might be equal in its effects to luminal is understandable, but the suggestion that "equally good results" may be obtained with it as with prominal seems to constitute to my mind rather a forcible dismissal of Dr. Millman's careful paper.—I am, etc.,

London, W.1, Aug. 9 RIPLEY ODDIE.

SIR,—In the *Journal* of August 7 (p. 295) Dr. R. Eager refers to his report on the Devon Mental Hospital for 1934, in which he says (page 26):

> "Prominal has been tried on cases which had been treated by luminal without success, but did not produce any strikingly different results. Phenobarbitone soluble, the British equivalent of luminal, is now being used with equally good results. It costs 2s. 6d. per ounce, while luminal, manufactured abroad, costs 14s. per ounce."

Prominal (Bayer) is listed at 250 tablets for 18s. 6d., while phenobarbitone soluble in 1½-grain tablets (Parke, Davis and Company) costs 20s. 6d. for 500 tablets, or 10s. 3d. for 250. But it is the daily cost of treatment which matters, and the benefit the patient obtains in fewer fits and lessened confusion. Dr. Millman has reported a reduction of one-third in the number of fits in a year under prominal, and Dr. Henderson a 67.3 per cent. reduction (*Journal*, July 10, pp. 61 and 63).

My own results in ten selected cases show a reduction in fits of 81.5 per cent. in 917 fits during one year's treatment with prominal. The average daily cost was 0.83d. for each of these patients, as supplies of prominal were obtained in bulk at a much reduced price.—I am, etc.,

L. G. MILLAR PAGE,
Norwich, Aug. 11. Senior Medical Officer, Hellesdon Mental Hospital.

SIR,—I was interested to read Dr. R. Eager's letter in the *Journal* of August 7 (p. 295). He quite correctly draws attention to the cheapness of phenobarbitone soluble, but phenobarbitone soluble is sodium phenyl-ethyl-malonyl urea (similar, that is, to sodium luminal), and is not prominal (N-methyl-ethyl-phenyl-malonyl urea), for which I have not yet found a "home-made" substitute.—I am, etc.,

Lancaster, Aug. 15. C. J. HENDERSON.

Decline of National Intelligence

SIR,—I have never before written to expostulate over a review of one of my books, but as, shortly after the appearance of my monograph, *The Fight for our National Intelligence*, you have given space to a review of it which is inaccurate and misleading, I trust you will do me the justice of inserting this reply.

As the soundness of the statistics on which I base my conclusion that national intelligence is declining has withstood the test of examination by no less an authority than Professor R. A. Fisher, I do not think it is necessary to defend here in detail the scientific validity of my results. The criticism that "controls were lacking" may seem to the casual reader to imply a serious error of method, whereas in fact it implies that the critic understands neither scientific method nor statistical technique. In what sense could a control group function in this experiment? Sampling was so devised so as to be free from any systematic error, whilst the size of the population—3,734 families—was such that the probable error of the difference of the means for the two generations was negligibly small in comparison with the difference actually found. Likewise, the taunt that Major Leonard Darwin begins his introduction with an absurdity reveals only that the critic cannot distinguish a true paradox from a common absurdity. If "the very title of the book suggests a bias," so, too, to take a greater example, does Darwin's *Descent of Man* and every scientific monograph which makes the trend of its findings clear in its title.

Naturally I am delighted to hear that other and more extensive investigations are now to be made into this problem, which (I may be biased to think) is the most grave of all those with which our national life is now faced. But I can see no justification for the critic adding, gratuitously, from the vantage point of esoteric knowledge and the unassailable retreat of anonymity, that these are definitely "more scientific inquiries." Nor can I see any reason for taking Lord Horder to task when he speaks of the present results as constituting a "discovery."

Finally, the review contains some misleading inaccuracies—as, for example, that my definition of the "social problem group" includes "most of our elementary school children." I specifically state (*on p. 107*): "*It is my* contention that the 'social problem group' . . . is the less fortunate half of the subcultural fifth"—that is, that it constitutes one-tenth of the school population.—I am, etc.,

Leicester, Aug. 7. R. B. CATTELL.

In Search of Health

SIR,—In a recent issue you published a letter from me quoting the advice of Hippocrates on the necessity of studying the habits of diet of patients. Dr. R. A. Young, in his article "Perspective and Poise in Practice" also refers to this matter. I am sending the notes of a case that seems to illustrate the value of this advice.

A girl aged 10 years and 11 months was examined at the dispensary as a suspected case of tuberculosis. She was referred to me by the school medical officer on account of recurrent cough, poor appetite, and lassitude. Her mother gave the following history. The patient had had a cough from the age of 4 years and had been treated for bronchial catarrh at the out-patient departments of three different hospitals (the out-patient cards were produced)—1927, a children's hospital for two years; 1931, a chest hospital; 1934, a general hospital—and in 1935 at a school clinic (for swelling of neck). She had six weeks' convalescent treatment on the Isle of

Wight, but no benefit was obtained. She was at Clacton for a period of twelve months to December, 1934, and was very much better on her return.

She was examined at this dispensary on July 1, 1935. There was no evidence of tuberculosis; no bronchitis; only post-nasal catarrh. The chief symptoms were cough, some spitting, marked loss of appetite, refusal of all green vegetables, salads, and fats. The patient had never eaten cabbage, except when at Clacton. The mother stated that at two hospitals she was advised to give the child whatever food she asked for. Admission to a residential open-air school was advised with the express purpose of correcting the faulty dietetic habit and establishing a healthy habit. On her return five months later the mother reported that the child was eating all that came her way. The following is the weight record: July, 1935, aged 10 years 11 months, 74 lb.; October, 1935, 79 lb.; June, 1936 (after five months at open-air school), 93 lb.; November, 1936, 98 lb.; June, 1937 (weight of a girl two years older), 105 lb. On her last visit the mother reported that the child was eating green vegetables and fat, but refused lettuce.

The pilgrimage of mother and child in search of health, patiently pursued for seven years from one out-patient department to another of both general and special hospitals, relieved by sojournings in distant seaside resorts, recalls Maeterlinck's fantasy, *The Blue Bird*. The characters, Tyltyl and Mytyl, after many fruitless journeys in search of the blue bird of happiness, return home and discover that their own bird at home is the blue bird. The girl and her mother are discovering that the food on her plate, particularly the humble despised cabbage, is the source of health. It would appear that refusal to eat green vegetables and fat (green shyness and fat shyness) in this case was due chiefly to the swallowing of catarrhal products. In other cases it is, apparently, a behaviour disorder, and needs to be studied and treated accordingly.—I am, etc.,

P. A. GALPIN,
Tuberculosis Officer, Plaistow.

London, E.13, Aug. 9.

Radio Interference due to Electromedical Apparatus

SIR,—The Committee of the British Standards Institution is inquiring into radio interference caused by electromedical equipment. We have been asked to obtain replies to the following questions: (*a*) has mechanical rectification any advantage over valve rectification in any particular cases, and if so, what are the advantages, and in what cases do they arise; (*b*) how far is it desirable, apart from economic considerations, to use spark apparatus for diathermy?

We shall be glad if any of your correspondents could give us information that would help us to answer these questions.—We are, etc.,

RUSSELL J. REYNOLDS.
GEORGE F. STEBBING.

Lambeth Hospital, Brook Street, Kennington Road, S.E.11, Aug. 5.

Wanted: Old Instruments for Extracting Teeth

SIR,—As honorary curator of the odontological section of the Royal College of Surgeons Museum, may I appeal to your readers for the gift of old types of instruments for the extraction of teeth, more especially those instruments in use during the early part of the last century?—I am, etc.,

FRANK COLYER.

London, S.W.2, Aug. 12.

Obituary

JOHN GORDON THOMSON, M.A., M.B., F.R.C.P.

Professor of Medical Protozoology, London School of Hygiene and Tropical Medicine

We regret to announce that Professor John Gordon Thomson, Director of the Department of Medical Protozoology at the London School of Hygiene and Tropical Medicine, died on August 13. The son of the late Mr. William Thomson, F.E.I.S., Professor Thomson was educated at Bathgate Academy and Edinburgh University, where he graduated M.A. in 1903. In 1904–5 he was awarded medals in botany and physiology. He was senior Mackenzie bursar in anatomy, and acted as prosector to Professor D. J. Cunningham in 1905. In 1908 he qualified M.B., Ch.B. (honours) at Edinburgh, and in 1930 took his M.R.C.P.London, being elected a Fellow last year. Two years after qualification Thomson was appointed Durning-Lawrence research fellow in tropical medicine at Liverpool, and in 1912 pathologist to the Royal Southern Hospital in that city. He was also clinical and pathological research fellow at the Liverpool School of Tropical Medicine from 1912 to 1913, and in the latter year was appointed assistant honorary physician at the Liverpool Chest Hospital. After receiving a Beit Memorial research fellowship he came to London as lecturer in protozoology at the London School of Hygiene and Tropical Medicine. In 1915 Thomson went on a bilharzia mission to Egypt, where he served as a captain in the R.A.M.C., and acted as protozoologist to the Central Military Laboratory in Alexandria and as pathologist to the Seventeenth General Military Hospital. On his return to England he was appointed officer in charge of the malarial research laboratory at the War Office. He was secretary to the Section of Tropical Medicine at the Annual Meeting of the British Medical Association at Cambridge in 1920. In 1926 he was exchange lecturer in protozoology at the School of Hygiene, Johns Hopkins University. In 1930 he was a representative at the third International Congress on Malaria at Algiers, and at the request of the League of Nations Health Organization he gave in 1936 a series of lectures at Singapore at the special League of Nations course on malaria.

Professor Thomson travelled widely in South America and other tropical countries. In 1921–2 he went on two expeditions to investigate blackwater fever in Rhodesia, and in 1924 visited the West Indies, Honduras, Guatemala, Costa Rica, and Panama. His experience in the field lent especial value to his writings and to his teaching, for which many students must feel a debt of gratitude. Professor Thomson's monograph on blackwater fever is one of the standard contributions on this subject, and his work on methods of enumerating malaria parasites in the blood and the study of cultural forms of the parasite are of the greatest importance.

Directness of approach to his subject, sound judgement, and common sense were characteristics of a man whose advice was sought by colleagues, who went to him the more readily on account of his friendliness and kindliness. His personal popularity and his professional reputation made it inevitable that visitors to this country interested in tropical medicine should seek him out, but, whatever the calls upon his time, he never spared himself in assisting others.

Professor Thomson married Hilda Burgess, and had one son and one daughter.

We are indebted to Sir Malcolm Watson of the Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, for the following appreciation:

John Gordon Thomson's death will be mourned as a personal loss by many, both at home and abroad, for Thomson was a great teacher as well as a scientist of distinction. His greatness as a teacher was due to a happy combination of qualities. In a supreme degree he had the gift of clear exposition. He himself saw clearly, for he was an accurate thinker; and it seemed no effort for him to say in simple words what he thought. Whenever he was available I asked him to lecture on the life history of the malaria parasite in man and the mosquito the malaria course for laymen. It was the opening ture in the course, and his fascinating account of this mplicated story, illustrated on the blackboard, held his dience spellbound. It was an admirable introduction the subject. Like so many Scotsmen, he spoke slowly d distinctly—of importance in one who lectured to any whose mother tongue was not English. Although ost of his life was spent in a laboratory, and although other ways he did not concern himself much with the siness side of life, yet he had a clear grasp of the actical bearings of what he taught, which made his aching of special value when the student came to study opical hygiene. But great as these qualities are, he ad another, of not less value alike to the student and ie School: he had a charity and a benevolence which owed themselves in the personal interest he took in is students, not merely as students but as men and omen, some of them in a strange land and far from riends and home. Can we wonder that it was for Professor Thomson that old students asked first when they eturned to the School? While he had no sympathy vhatever for the slacker, he was deeply concerned when n the examination pass list the names of some whom he hought should have got through were absent. As an examiner his object was to find out what a man knew by questions that helped rather than puzzled the candidate. He was unhappy when some of his colleagues seemed to adopt the other course, and he has told me how he sometimes tilted the balance in the candidate's favour in the subsequent discussion. All this was just part of the great-heartedness of the man, which endeared him alike to his students and his colleagues, and not least to Sir Ronald Ross, who had a specially warm side for both Gordon Thomson and his brother David. His friendship with Ross dated from the time when after a distinguished career at Edinburgh University he joined the staff of the Liverpool School of Tropical Medicine.

About the time he was clinical and pathological research fellow at the Liverpool School of Tropical Medicine he produced, by himself or in collaboration with Ronald Ross, his brother David, H. B. Fantham, and J. A. Sinton, a number of important papers on the enumeration and morphology of trypanosomes, the growth of malaria parasites in culture and in human beings, the cultivation of *Pyroplasma canis in vitro*, and the cultivation of human tumour tissues. A Beit fellowship brought him to London in 1913, where he worked on spirochaetes in the intestine of man and animals, and shortly after he joined the London School of Hygiene and Tropical Medicine, then at the Albert Docks. His appointment as officer of the Malarial Research Laboratory at the War Office again brought him into contact with Ross. The end of the war was not, however, the end of Thomson's travels and researches abroad. It might almost be regarded as the beginning. One of the most important of these was his research on blackwater fever in Southern Rhodesia, made during two visits to that country. In spite of the fact that his health was not quite as good as it might have been, he was off to Nyasaland in 1934 to study immunity in malaria, and spent nearly a year there, keeping a group of African children under constant observation and also interesting himself in trypanosomiasis and other subjects, on which he published reports on his return to London. As he told me not long ago, this last trip, with often unsuitable diet, taxed his strength severely, and at times he was tempted to cut it short—but he stayed the course.

In addition to his many scientific papers he published in 1929, along with Dr. Andrew Robertson, a textbook on protozoology for medical men, which has been of great value. Last year, when, under arrangement with the Ministry of Health, direction of the work of the laboratory at Horton Malaria Therapy Centre was undertaken by the London School of Hygiene and Tropical Medicine, Professor Thomson's special qualifications fitted him to take over its general control and supervision. He was just beginning to get into his stride with this work when, at the beginning of this year, he became far from well, and went into hospital with a gastric ulcer. For some months he improved, and the School saw the familiar figure again for a few weeks. But an internal haemorrhage pulled him down again, and there was evidently something more serious in the background. This compelled his return to hospital. He bore his illness calmly and hopefully, and only the order that he should see fewer people limited the numbers who called to see him.

In an obituary article in the *Times* of August 16 his colleague, Sir Rickard Christophers, wrote: "His name is very familiar also in work in the field of tropical medicine, and his contributions to science are known to research workers all over the world. Perhaps his most outstanding personal characteristics were his readiness to enter into the scientific interests of others and to spare himself not at all in doing whatever was possible to assist their work." Such a man could not fail to leave a fragrant memory to a host of friends.

NORMAN MACLAREN, F.R.C.S.

Consulting Surgeon, Cumberland Infirmary

Mr. Norman Maclaren of Carlisle died on August 12 at the age of 61. He was educated at Carlisle Grammar School, Rugby, and at Trinity College, Cambridge, where he took first-class honours in the Natural Science Tripos in 1897. He qualified M.B., B.Ch. in 1901, and in the same year received the diplomas of M.R.C.S.Eng., L.R.C.P.Lond., and two years later was elected F.R.C.S. From Cambridge Mr. Maclaren went to St. Bartholomew's Hospital, and later to the Metropolitan Hospital, as house-surgeon. He then joined his father, first as an assistant and then as partner, in his practice in Carlisle. Mr. Maclaren was

appointed to the staff of the Cumberland Infirmary as assistant surgeon in 1904, acted as surgeon from 1912 to June, 1936, when he retired as consulting surgeon. On the death of Mr. E. W. Stead he was elected honorary treasurer of the infirmary, and in that capacity continued to render valuable service to the hospital; he was also consulting surgeon to the Border Counties Home for Incurables and the Cumberland and Westmorland Convalescent Home at Silloth. Mr. Maclaren was an active member of the British Medical Association, which he joined in 1903. He was honorary secretary of the Border Counties Branch from 1922 to 1926, president in 1925–6, and assistant honorary secretary in 1926–7, and had previously served as chairman of the English Division in 1919–20. On eight occasions between 1920 and 1935 he acted as representative at the Annual Representative Meeting. He was assistant county commissioner of the St. John Ambulance Brigade, a Serving Brother of the Order of St. John of Jerusalem, and county controller for Cumberland and Westmorland V.A.D.s. He was appointed a justice of the peace for Cumberland in January, 1927, and in December, 1933, was elected chairman of the Cumberland Ward magistrates. At the outbreak of the great war Mr. Maclaren held a commission in the old 1st Volunteer Battalion of the Border Regiment, and proceeded with his battalion to Burma. In 1916 he was transferred to Bombay, where he worked at Colaba Hospital as a major in the R.A.M.C.; he afterwards served in Egypt. On his retirement he was gazetted *lieutenant-colonel* and received the Territorial Decoration. He continued to be a military member of the Territorial Army Association of Cumberland and Westmorland. Mr. Maclaren contributed articles to the *British Medical Journal* on "Cumberland Infirmary—Past, Present, and Future" (1925), "Addison and Cumberland" (1926), and "Lister and Carlisle (1927). Mr. Maclaren is survived by a widow and two sons, one of whom is a house-surgeon at St. Bartholomew's Hospital.

A colleague and friend writes:

In the passing of Norman Maclaren the profession and community have lost a good friend, for Maclaren's life was essentially one of service. His lifelong interest has been the Cumberland Infirmary. From boyhood, as a son of Roderick Maclaren, a former surgeon, he had been schooled in its traditions, and he completed his full term of service as surgeon only last year. Maclaren was also untiring on committee, and latterly was never happier than when as treasurer of this institution he could present a favourable balance sheet. The Maclarens had always carried on a general practice in addition to their surgical work, so that Norman Maclaren leaves many patients who will find a blank in their lives, for he was often very much more than their professional attendant, guiding and advising in many family crises. Those of us who served with him in Burma and India throughout the war will always remember gratefully his interest, professional and personal, in the welfare of all ranks. In latter years his archaeological interests had brought him much in contact with the recent work on the Great Wall of Hadrian, while his work in heraldry had resulted in the production of the arms of all the former Bishops of Carlisle. Carlisle is the poorer for his passing, but, using his own oft-repeated phrase, we must "carry on."

Mr. J. N. J. HARTLEY writes:

The passing of Norman Maclaren has deprived Carlisle of a leading member of the medical profession, and will occasion sorrow to numerous devoted patients and to a wide circle of friends and colleagues. For more than thirty years he has been a member of the honorary surgical staff of the Cumberland Infirmary. It was only last year, on attaining the age limit, that he ceased active membership on the staff and was appointed honorary consulting surgeon. Though he retained a keen interest in practical surgery, his energies during recent years have been largely devoted to the administrative side of the institution. As honorary treasurer and an enthusiastic member of numerous hospital committees he has rendered invaluable service, and he has taken a large share in introducing schemes for the further extension of the Cumberland Infirmary, and especially for launching the new operating theatre fund. In the future his memory will be linked chiefly with the Cumberland Infirmary.

He had a rich store of memories of his school days at Rugby, of Cambridge, of St. Bartholomew's Hospital, of surgery in the time of his distinguished father, and of his own experiences in Burma and Egypt during the great war. As hobbies he had great interest in and knowledge of heraldry and archaeology. We shall treasure memories of Norman Maclaren as a genial companion, a loyal colleague, one reluctant to believe, and never uttering, anything but good of his fellows, and zealously devoting time and energy to voluntary medical service.

MARTIN H. OLDERSHAW, M.D., F.R.C.S.

Surgeon, Hospital for Women, Soho Square

We announce with regret the death, at the age of 46, of Dr. Martin Herbert Oldershaw of Upper Wimpole Street. Dr. Oldershaw began his education at the Brighton Technical College, and entered University College Hospital after winning the Bucknill scholarship. He graduated M.B., B.S. in 1917, and in the same year was appointed to the resident staff of University College Hospital, occupying in succession the posts of house-physician, house-surgeon, obstetrical registrar, and casualty surgical officer. In the course of these appointments he proceeded to the M.D. with a gold medal in 1919, becoming at the same time a Fellow of the Royal College of Surgeons. His interests were chiefly obstetrical and gynaecological, and he was appointed to the staff of the Soho Square Hospital for Women. Later he became consultant obstetrician and gynaecologist to the London County Council, and consultant gynaecologist to the British Red Cross Clinic for Rheumatism and to St. John's Clinic. He was also consultant obstetrician to the St. Pancras Borough Council, and examiner to the Central Midwives Board and General Nursing Council of England and Wales. Dr. Oldershaw was a Fellow of the Royal Society of Medicine, and he played an active part in the work of the Obstetrical and Gynaecological Section. For four years Dr. Oldershaw was honorary secretary of the Hunterian Society. He published one or two articles in professional journals on the treatment of cancer of the uterus, and on the significance of bleeding as a symptom in gynaecology. A keen Mason, he had held many Masonic appointments, including the Mastership of the Aesculapius Lodge. He is survived by his wife and a young son.

The sudden death of Dr. EDMUND WELCH on August 2 removed one of the best-known personalities in the medical profession in Leeds. Dr. Welch, who was in his sixty-eighth year, was born in Morley. On qualifying in 1895 he settled down in Stanningley, where he remained in active practice till the day of his death. He became a member of the British Medical Association in 1912, and there found an outlet for the dominating interest in his life—service for his fellow practitioners. He did very important work for the profession in the early days of the National Health Insurance Act and during the war, which was recognized by his election as representative in 1925, in which capacity he acted until his death. He was chairman of the Leeds Division in 1929–30 and president of the Yorkshire Branch the same year. His association with the Insurance Acts Committee began in 1927, and he devoted himself whole-heartedly to his duties. He was appointed to so many subcommittees that it was a mystery how he found time for them. It was a certainty that if he ever failed to attend one it was because he was present at some other. Dr. Welch's charming personality endeared him both to his patients and to his fellow practitioners. If he had to offer adverse criticism he did so in such a quiet, gentle manner that it never failed to carry great weight. He died as he would have wished to do—in harness: he had finished his day's work before being seized by a heart attack. Dr. Welch is survived by a widow and two sons, one of whom was in partnership with him.

Dr. PATRICK P. J. GANTÉAUME, M.B.E., one of the best-known practitioners and public men in South Africa, died at East London, Cape Province, on July 31. He studied at Edinburgh University and graduated M.B., C.M. in 1899. After a year and a half as house-surgeon and assistant in Sunderland he went off to the Boer War, being attached as surgeon to the Highland Light Infantry. After the war he settled in East London, and there built up a large surgical and general practice. During the great war Dr. Gantéaume was attached for some time as a surgeon to No. 1 General Hospital, South Africa. A gifted speaker and fluent French scholar, he loved public affairs, and was re-elected mayor of the city of East London for several consecutive years. Dr. Gantéaume had been in failing health for the last few years, but in spite of a painful duodenal ulcer he bravely carried on a small portion of his old practice to the end. At the Annual Meeting of the British Medical Association at Aberdeen in 1914 he acted as representative of his Division.

We announce with regret the death of Dr. HERBERT CHRIPPES UPTON of Hove in July of this year. He was the oldest practitioner in Sussex, having reached the age of nearly 93, and was doing his work till within a few days of his death. Dr. Upton received his medical education at St. Bartholomew's Hospital, where he won the Foster prize, and was a scholar in medicine, surgery, and forensic medicine. He took his M.R.C.S. in 1866, taking the L.R.C.P. in the following year. He was appointed resident medical officer of the Brighton and Hove Dispensary and settled down in practice in Hove nearly fifty years ago. He took a great interest in municipal affairs, was elected a member of the Hove Town Council, and later became an alderman, which office he held at his death. His medical knowledge was much valued by his colleagues on the many committees on which he served. He gave his time and services willingly and freely to the work of the council for a period of well over forty years. Dr. Upton took a great interest in the game of bowls, and was often to be seen at the Hove Bowling Club during his periods of recreation. His funeral was attended by a large number of his friends, patients, and colleagues, including the Mayor of Hove and many aldermen, councillors, and officials of the Hove Corporation, an eloquent testimony to the regard, esteem, and affection in which he was held. Dr. Upton took no special part in the work of the various medical societies of the town, but his quiet, unostentatious devotion to the interests of his patients endeared him both to them and to his fellow practitioners. He leaves behind him the memory of a life of useful work, carried on for so many years in the best tradition of our profession.

The death of Dr. EDWARD MERRY of Brighton removes a well-known and much-respected member of our profession from our ranks. Dr. Merry took the M.R.C.S., L.R.C.P. in 1899, after having studied for a short period at the London Hospital. In the following year he proceeded to the M.D. of Western University, Ontario, where he had received the early part of his medical education. He settled in Brighton, and practised there for some twenty years before retiring. He took a special interest in midwifery, and was well known for his experience in that branch of medicine. He will be remembered, too, by thousands of holiday-makers and Brighton people as the doctor who, until he retired from practice five years ago, went down to the beach to preach at the open-air mission. Dr. Merry was a member of the Plymouth Brethren, and his vigorous sermons were a feature of life on the Brighton front. His funeral took place on August 11, and was attended by many colleagues, patients, and friends. He leaves a widow and five children, to whom the sympathy of his colleagues in Brighton is extended.

Medico-Legal

PUERPERAL FEVER IN A COTTAGE HOSPITAL

Damages Awarded to Patient

A young Leicestershire woman was recently awarded heavy damages against the Ashby-de-la-Zouch Cottage Hospital and her general practitioner for injuries due to puerperal fever, which she contracted in the hospital.*

At the Derbyshire assizes, held in July before Mr. Justice Singleton, Mrs. Marjorie Heafield sued Mr. C. E. Crane, chairman of the hospital, and Dr. J. W. Hart of Measham for negligence. She alleged that before her illness she had been a healthy and active woman and a good tennis player. She was married in 1933, and entered the hospital on January 5, 1936, as a paying patient, for her confinement. The child was born in the "old labour ward" in the presence of Dr. Hart and Sister Maud Seymour, who was not wearing an overcoat, mask, or gloves, and had been attending a Mrs. Ingham, who had on the previous day shown symptoms of puerperal sepsis. The hospital was understaffed, and Mrs. Heafield was left some hours in the old labour ward without proper attention. She was then removed to the "general ward," which contained three other women, including Mrs. Ingham, with whom she was eventually notified as a case of puerperal sepsis. On the evening of January 6 her temperature was 101.4° F.; next day it was 102.8°, and in the evening it rose to 104.6°. On January 8 Dr. Hart notified her. Until January 18, however, her husband was told that her case was proceeding normally. He then became alarmed and sought out Dr. Hart, who confessed that he was a little worried. The husband then asked for a specialist. Dr. C. O. Lochrane, a gynaecologist, was sent for and had her removed to a Derby hospital for treatment. She recovered, having received transfusions of blood; she was now totally crippled and not expected to have anything like normal function restored.

Mrs. Ingham said in evidence that she had been confined in the hospital on January 1, that the nurse did not wear

* For the above account we are chiefly indebted to the *Leicester Evening Mail* for July 13–17 and 30.

gloves or mask and that Dr. Hart had told her that she and Mrs. Heafield were suffering from the same disease. Mr. Heafield said in evidence that on January 8 his wife had complained of being hot, and on January 18 she was partly delirious. Her weight had fallen from just over 9 st. to 5 st.

Sir Bernard Spilsbury said that the hospital case-book showed quite clearly that there were notifiable puerperal cases at the hospital. Such cases should be isolated and no other patients should be admitted into the ward until it had been thoroughly cleansed and sterilized. Nurses should have their clothing covered by sterilized gowns and wear masks and gloves. Inquiry should be made for the possibility of infection among other patients, and to take swabs might be a wise precaution. A nurse could carry infection. Mrs. Heafield should not have been admitted to the hospital. He would not allow a woman to come into a ward where there was another woman with a temperature of 104° F. Nothing but sepsis could account for an intermittent temperature ranging from 102° F. in a puerperal case. A temperature of 104° F. was gravely suspicious of puerperal fever. The charts prepared for the action contained a clear indication of puerperal fever and showed that no healthy patient should have gone into the ward.

Dr. J. L. Berry, lecturer at Birmingham University, who had prepared the charts produced by Sir Bernard Spilsbury, said they showed that the patients whose temperatures they represented had notifiable pyrexia and that the general character of Mrs. Heafield's record indicated a streptococcal infection. Mrs. Heafield was at the time of the action still strapped and bandaged to a steel frame; her legs were moved outwards and her right wrist was rigid with only very slight movement. The right shoulder and head could be moved. She would probably be a permanent cripple and would hardly be able to walk. Her condition was due to puerperal sepsis.

Dr. G. B. Gill, general physician, Leicester, said he had formed the conclusion, by examining the case-books of the hospital for the three weeks before Mrs. Heafield's admission, that it was a "seething hotbed of mixed infection." Cross-examined, he admitted that a large number of patients had no temperatures, but observed that resistance varied greatly. He thought Dr. Hart should have had Mrs. Heafield isolated with a special nurse when her temperature rose.

The Case for the Hospital

Counsel for the hospital, after opening his case, called Sister Seymour, who said that she was second in command. Temperatures were taken at 6 a.m. and 6 p.m., and the charts were always available for the doctors. There were about twelve beds in the maternity unit. Dr. Hart had always seen the charts. Mrs. Ingham had had a temperature the evening before Mrs. Heafield was admitted. As a qualified midwife she realized that a temperature might be significant. She wore only a mackintosh apron and never wore a mask, gloves, or overall without instructions. There was a supply of gloves and masks for use if required and a special supply of mackintosh aprons. Dr. Hart had worn one of these. Nurses always went and scrubbed their hands immediately after attending a patient's dressing. After Mrs. Heafield's baby was born the sister thought she saw her crying, but Mrs. Heafield said she had a cold. Cross-examined, she agreed that nurses had in recent years been taught much about the danger of septic infection, and that she knew the danger-flag was temperature and had been taught that a temperature of 100.4° persisting for twenty-four hours was probably due to sepsis. On the matron's instructions she had written in her report after the action had begun, "Appears to have a cold."

Dr. S. C. M. Davison, a general practitioner of Ashby, said that he had attended the hospital for ten years, and, speaking generally, had never had any cause for complaint against the hospital or staff. Changes of temperature were immediately notified.

Dr. H. H. Silley stated in cross-examination that the medical staff of the hospital had held a meeting on January 22, at which Dr. Hart had been present, to discuss the best method of preventing any further cases of puerperal sepsis. It had been decided that there was one undoubted case, that of Mrs. Heafield. He maintained that the routine of the hospital was not known to be faulty.

Mrs. Anne Warren, superintendent health visitor for Leicestershire, said that as a result of Dr. Hart's notification she had visited the hospital on January 14. She had seen Mrs. Ingham's temperature chart and formed the opinion that she was suffering not from puerperal fever but from mastitis. Mrs. Heafield's chart showed that her temperature was 100.4° F. or 100.6° F. on the evening of her confinement, and therefore suggested that whatever germ she had had she had brought in with her. There was not sufficient swing for a typical puerperal fever chart. She had remarked to Mrs. Heafield, "You have a cold," and Mrs. Heafield had answered, "Yes, I had it a day or two before I came in." Her definite opinion was that Mrs. Heafield was suffering from influenza, which had been very rife at that time. She had no criticism of the maternity administration of the hospital.

Miss Alice Arkinstall, the matron, said there was no resident doctor and the medical staff were purely honorary. If a patient developed a temperature it was the custom to ring up her doctor. She did not suspect Mrs. Heafield of puerperal fever until the superintendent health visitor had come. Dr. Hart had never told her to inform the other doctors of the condition of Mrs. Heafield. If she had been suspicious she would have informed them. During her six years in the hospital 650 babies had been born without the loss of a mother. In answer to the judge, she said that Dr. Hart had never suggested that Mrs. Heafield ought not to have been placed in the same ward as Mrs. Ingham. He had not been kept from seeing the charts of other patients. Cross-examined, she said that the entry "Appears to have a cold" was put into the case-book when the solicitor had first come to see her "just to remind her." This was not "a terrible thing to do," and she had not realized that it might be a part of her defence.

Dr. W. E. Barnie-Adshead of Birmingham said that in his opinion Mrs. Ingham had not suffered from puerperal fever and Mrs. Heafield had been infected before ever Dr. Hart delivered her; and that she had not suffered from the same type of disease as Mrs. Ingham, who therefore could not have infected her. Dr. Hart ought to have isolated Mrs. Heafield when her temperature rose and proceeded with investigations. Having regard to the charts and case-book, it was not safe to put her in the same ward as Mrs. Ingham, although Mrs. Ingham might have been suffering only from a simple complaint.

Counsel for Dr. Hart called and examined Dr. J. P. Hedley of St. Thomas's Hospital, who said that puerperal fever covered three classes of disease, and that, from the case-book and charts, Mrs. Ingham's temperature was caused by a different germ from that of Mrs. Heafield, who was probably not infected in hospital by puerperal fever. If she had been she would almost certainly have died. Puerperal fever was often caused without outside infection. Dr. Hart had done everything possible in the treatment of Mrs. Heafield. He agreed, in answer to the judge, that if infection were about gloves and a mask should be worn by everyone attending the patient.

Dr. Francis Allen of the Cripples' Hospital, Birmingham, stated that Mrs. Heafield had had two operations since December, and would not be able to walk or sit down naturally again. Her hips were completely stiff.

Dr. Hart's Evidence

Dr. Hart testified, in his own defence, that he had taken the usual precautions in attending Mrs. Ingham. He had not worn gloves, because he did not do so in a normal case. After he had left her he had not known where in the hospital she was placed. At that time he had no knowledge of any patients with temperatures, or of suspected puerperal infection. She had been normal on January 2 and 3; he had not visited her on the evening of January 4, but on the morning of January 5 had found that she had had a temperature the night before. He had been very annoyed, and had asked the matron why he had not been informed. He had suspected

that Mrs. Ingham had some puerperal infection. He had treated her on January 8 and notified her case to the medical officer of health; her condition had improved, and on January 19 she had been discharged. He was still her medical adviser. Mrs. Heafield's confinement had been normal. He had visited her on January 6 and again on January 7, when he had found that her temperature had risen the night before. This had not been reported to him, and he had become very alarmed. He had begun to suspect puerperal infection, and decided to notify Mrs. Heafield's case as well. He had told the matron this and discussed with her the steps to be taken to stop the spread of infection, saying that other doctors must be told. On January 8 or 9 the hospital temperature charts had shown that two other patients were running temperatures. He had told the matron that this looked "something very bad." He had never thought that Mrs. Heafield contracted her infection from Mrs. Ingham. He admitted in cross-examination that he knew very little about puerperal fever and supposed that he had wasted about a couple of days. These were the first two cases that he had ever had go wrong. He could only suggest one instance of negligence of a nurse during the confinement of these women: she had walked from one to another without washing her hands. After he had notified the cases and spoken to the matron the whole atmosphere of the hospital had changed towards him: he had not received the same courtesy as before. For ten years he had been attending four or five patients a year there, but since the action had begun he had not had any. Three of his patients had asked to be confined in the Ashby hospital under his attendance, but the matron had said that the hospital was full. This might or might not have been correct. He had not interfered with the regular routine of the hospital, and had no idea which ward Mrs. Heafield would go to.

The Judgement

The learned judge reserved his judgement and delivered it in London on July 30. He said that he was satisfied that Mrs. Heafield was not suffering from a cold when she entered the hospital, because if she had been Dr. Hart would have noticed it. It was most unfortunate that the addition, "Appears to have a cold," should have been made to what was supposed to be a record of the case made at the time, and he could not accept the statement of the matron that "it was just to remind me." He also rejected the evidence of the superintendent health visitor, Mrs. Warren, that Mrs. Heafield said she had a cold before she went into hospital. He believed that Mrs. Heafield was perfectly well when she entered the hospital, and the first sign of anything being amiss had been on the evening of January 6, when her temperature had been 101.4° F. Although Dr. Hart had notified the case on January 8, and on that day written a letter to the secretary of the hospital, he had not said a word to Mr. Heafield until on January 18 he had found her flushed and delirious and had suggested a second opinion. His lordship was satisfied that Dr. Hart had been right in diagnosing Mrs. Heafield's case, and also Mrs. Ingham's case, as being due to puerperal fever. Mrs. Heafield had caught the infection from Mrs. Ingham through being placed in the same ward with her without special precaution. There had been at the hospital complete disregard of the statutory regulations, which required cases of puerperal pyrexia to be notified. To say the least, it was regrettable that so little attention seemed to have been paid to the regulations, and it was in Dr. Hart's favour that he had reported his two cases on January 8. The hospital staff had failed in their duty through placing Mrs. Heafield in a ward where there was a gravely suspicious case, and Dr. Hart had failed in his duty by not isolating Mrs. Ingham. Women were encouraged to go to hospitals and nursing homes for their confinements because of the better facilities for cleanliness and safety, but Mrs. Heafield would have been far safer at home. He awarded her £3,500 general damages and £149 special damages against Dr. Hart and Mr. Crane jointly, but against Mr. Crane in his representative capacity only.

Dr. Hart's defence was undertaken by the London and Counties Medical Protection Society.

Universities and Colleges

UNIVERSITY OF LONDON

Recognition of Teachers

The following have been recognized as teachers of the University in the subjects indicated in parentheses:

London Hospital Medical College.—Mr. D. W. C. Northfield (Surgery).

Guy's Hospital Medical School.—Mr. R. C. Brock (Surgery); Dr. R. W. B. Ellis (Children's Diseases); Dr. C. P. Symonds (Medicine).

St. Mary's Hospital Medical School.—Mr. A. E. Porritt (Surgery).

King's College Hospital Medical School.—Mr. A. W. Kendall (Surgery).

University Readership in Biochemistry

The Senate has resolved to institute a University Readership in Biochemistry tenable at the Lister Institute of Preventive Medicine in accordance with the Regulations on University Titles (*Calendar*, 1936-7, pp. 259-70).

Dixon Fund

Dr. C. S. Hallpike has been granted £15 from the Dixon Fund towards the cost of an automatic knife-grinding machine in connexion with a histological examination of the temporal bone, and Dr. Giulio Stella £30 from the same Fund for the purchase of apparatus and materials to aid an investigation on the respiratory central mechanism, the researches to be carried out at Middlesex Hospital and in the physiology department of University College respectively.

Thomas Smythe Hughes Medical Research Fund and Beaverbrook Fund

The following grants, amounting in all to £200, have been made out of the Thomas Smythe Hughes Medical Research Fund and the Beaverbrook Fund for 1937-8, for research to be carried out at the college or hospital designated:

To Dr. Harold Muir Evans, £50 to be spent on the technical preparation of microscopic specimens to aid a comparative study of the brain of Teleostean fishes, with special reference to their habits and the study of seasonal changes in the pituitary gland of fish (Anatomical Department, University College, and in own laboratory).

To Mr. Roderic Alfred Gregory, M.Sc., £30 for the purchase of materials in connexion with investigations of the metabolism of the isolated mammalian heart, with special reference to carbohydrates, in normal and hyperthyroid animals (Department of Physiology, University College).

To Dr. Richard Wheeler Haines, £30 for the purchase of materials in connexion with a revision of the forearm muscles in a number of primitive animals (Department of Anatomy, St. Thomas's Hospital).

To Mr. John Marshall Ledingham, B.Sc., not exceeding £30 for a dissecting microscope and for the purchase of materials in connexion with an investigation into the mode of initiation and propagation of an impulse set up in a nerve fibre by electrical stimulation (Department of Biophysics, University College).

To Professor Bryan Austin McSwiney, £15 for materials for research on (1) visceral afferent pathways, and (2) reflex mechanism controlling pancreatic secretion (Sherrington School of Physiology, St. Thomas's Hospital).

To Dr. Walter Roworth Spurrell, £20 for the purchase of a microtome for serial sections in connexion with a research on the output of prolan and oestrin in the normal and pathological cycles of menstruation and pregnancy (Physiology Department, Guy's Hospital Medical School).

To Professor Samson Wright, £25 towards the cost of a Keith Lucas pendulum and accessories for the continuation of research on the action of acetylcholine and related substances and of anticholinesterases on the central nervous system (Middlesex Hospital Medical School).

The Senate has resolved that students who have passed the B.Sc. (Household and Social Science) Examination be exempted from the Second Examination for Medical Degrees, Part 1, and that the Regulations for Internal Students (*Re-*

Book, 1936-7, p. 263) be amended accordingly, and that students who have passed the M.B., B.S. Examination be exempted from examination in pathology and bacteriology at the B.D.S. Examination, and that the Regulations for Internal Students' (*Red Book*, 1936-7, p. 301) be amended accordingly.

The Ph.D. Degree in Physiology has been awarded to Robert Laing Noble, M.D. (Middlesex Hospital Medical School), and the D.Sc. Degree in Physiology to Mrs. Marion Grace Eggleton, M.R.C.S., L.R.C.P. (University College).

Dr. F. D. Turner has been appointed governor of Colchester Grammar School.

Professor T. B. Johnston, who has held the University Chair of Anatomy tenable at Guy's Hospital Medical School since September, 1919, having been appointed superintendent of Guy's Hospital on the resignation of Mr. H. L. Eason, the Chair has been replaced by a part-time Chair tenable at the School, and Professor Johnston has been appointed thereto as from October 1. Professor Johnston has relinquished the office of Dean.

The Services

DEATHS IN THE SERVICES

Lieut.-Colonel JOSEPH FRANCIS WHELAN, D.S.O., O.B.E., R.A.M.C. (ret.), died at Hove early last month, aged 64. He was born on March 1, 1873, was educated at the Catholic University, Dublin, and graduated as M.B., B.Ch., and B.A.O. in the Royal University of Ireland in 1896. After filling the post of house-physician of the Mater Misericordiae Hospital in Dublin, he went out to South Africa to serve as a civil surgeon in the South African War, in March, 1900, and took a permanent commission as lieutenant in the R.A.M.C. on November 14, 1900. He attained the rank of lieutenant-colonel on June 2, 1918, and retired on March 1, 1928. For some time after his retirement he was employed on the retired list at Warwick. Before he took up the study of medicine he served as an official in the General Post Office, Dublin; and in his youth was a well-known Association football player, playing full back for Leinster in the old Interprovincial tournaments. He served in the South African War from 1900 to 1902, taking part in operations in Cape Colony, the Orange River Colony, and the Transvaal, and received the Queen's medal with three clasps and the King's medal with two clasps. He also served throughout the war of 1914-18, when he was mentioned in dispatches in the *London Gazette* of March 12, 1918, and received the D.S.O. and the O.B.E. He was a member of the British Medical Association from 1903 to 1924.

Lieut.-Colonel JAMES DUNNE DAY, R.A.M.C. (ret.), died at Isleworth on June 18, aged 82. He was born on December 31, 1854, and was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., B.A.O., in 1878, subsequently taking the F.R.F.P.S. at Glasgow in 1888. Entering the Army as surgeon on March 6, 1880, he became lieutenant-colonel after twenty years' service, and retired on June 19, 1901. He served in the South African War in 1899-1901, when he took part in operations in Cape Colony and in the Orange River Colony, including the actions at Colesberg and Vet River, and he received the Queen's medal with three clasps.

Colonel WILSON RANSON, D.S.O. R.A.M.C. (T.F.) (ret.), died at Hull on July 31, aged 67. He was the son of Mr. Joshua Ranson, and was educated at Bradfield and afterwards at Edinburgh and at St. Thomas's Hospital. He took the Scottish triple qualification in 1894, and the F.R.C.S.Ed. in 1898. After serving as assistant surgeon at the Down County Infirmary at Downpatrick he joined the R.A.M.C. (T.F.), and in 1907 was placed in medical charge of the 15th Regimental District at Beverley. At the outbreak of war in 1914 he went to France, serving successively in command of the 3rd Northumbrian Field Ambulance in the 50th Division, the 47th Casualty Clearing Station in the Fifth Army, and the 30th General Hospital as A.D.M.S. of No. 1 Army Area, and finally as D.D.M.S. of the 4th Corps in the Army of the Rhine. He was twice mentioned in dispatches, in the *London Gazette* of January 1, 1916, and of January 1, 1917. He was twice wounded, and was specially promoted to the rank of colonel in December, 1917, and received the D.S.O. After the war he served as deputy commissioner of medical services at the Ministry of Pensions and as medical superintendent of the Ministry's hospital at Orpington. His chief recreation was hunting; in 1901-2 he was master of the Ashburden Harriers. He married twice and had one son.

Medical News

A notice appears in our advertisement columns this week inviting applications for the Chair of Anatomy in the University of Melbourne at a salary of £1,200 per annum. In another notice applications are invited by the London County Council for a coroner to fill the vacancy created by the death of Dr. Edwin Smith. The salary is £1,700 per annum.

The annual dinner of past and present students of St. Mary's Hospital Medical School will be held at Claridge's Hotel on Saturday, October 2, at 7.30 p.m.

Lord Hartington, in his presidential address at the annual meeting of the Devonshire Royal Hospital, Buxton, referred to a £30,000 scheme on which the committee of management had embarked, and said that these extensions were urgently necessary. The Marchioness of Aberdeen said there was still inadequate public recognition of the fact that rheumatic diseases were curable, although the International League against Rheumatism had collected records of wonderful work in thirty countries.

The sixteenth American Congress of Physical Therapy will be held in Cincinnati, Ohio, from September 20 to 24 at the Netherland Plaza Hotel, under the presidency of Dr. William Bierman of New York. Further information can be obtained from the editorial and executive officers of the Congress, 30, North Michigan Avenue, Chicago.

The thirteenth Medical Congress of the Alps will be held in Salzburg on September 24 and 25, when the chief subject for discussion will be the diagnosis, indications, and treatment of emergencies. Further information can be obtained from Dr. Rudolf v. Rauchenbichler, Schwarzstrasse 12, Salzburg.

The Annual Congress of German Neurologists and Psychiatrists will be held at Munich from September 20 to 22, when the following subjects will be discussed: cerebral tumour, epilepsy, and experiment in psychotherapy. Further information can be obtained from Professor Nitsche, Bezirk Dresden, Pirna.

The Jugoslav Medical Society will hold its annual congress at Novi-Sand from October 3 to 5, when the subjects for discussion will be acute infectious diseases, alcoholism, tuberculosis, and professional problems. Further information can be obtained from the secretary, Seleni Venaz 1 and 2, Belgrade.

An International Congress of Scientific Journalism will be held in Paris from October 7 to 9, under the auspices of the Ministry of Commerce and Industry, the fee being 25 francs. Among the questions set down for consideration are the communication of information to the lay press; the preparation and publication internationally of scientific reviews; and the status of scientific journalists. It is hoped at this congress to formulate proposals to place this branch of journalism on a more satisfactory basis, and to arrange for the popularization of the more important modern discoveries which have general practical implications. All inquiries should be addressed to M. Jules Toutain, the general secretary of this congress, 25, Rue du Four, Paris, VI.

The International Congress of Anaesthetics will be held at the Congress Hotel, Chicago, from October 25 to 28, during the Clinical Congress of Surgery. Further information can be obtained from the general secretary, Dr. F. H. McMechan, 318, Hotel Westlake, Rocky River, Ohio.

The seventh Italian Congress of Forensic Medicine and Insurance will be held at Naples from October 15 to 18, under the presidency of Professor Giuseppe Falco. The subscription is 30 lire. Further information can be obtained from the secretary, Via Luciano Armanni, 3, Santa Patricia, Naples.

A postgraduate course in the technical surgery concerned in the treatment of affections of bones, joints, and muscles will be held by Professors Ombredanne and P. Mathieu, in conjunction with other experts, and under the auspices of the University of Paris, from October 11 to 28. Special attention will be paid to modern operative technique, and there will be practical classes. Further information may be had from Professor Mathieu at the Clinic of Orthopaedic and Adult Surgery, Hôpital Cochin, Paris; the fee is 250 francs.

The Duke of Kent will visit Blackpool on October 21 to open the new hospital which has been built at a cost of £225,000.

The National Association for the Prevention of Tuberculosis have published a ninth edition of their *Handbook of Tuberculosis Schemes*. This forms a complete directory of the tuberculosis work in each administrative area of the United Kingdom, the Irish Free State, and the Channel Isles. The handbook may be obtained from the Secretary-General, N.A.P.T., Tavistock House North, London, W.C.1, and the price is 5s.

The return for 1936 of Vital Statistics of Non-native Officials in West Africa has now been published by the Crown Agents for the Colonies, 4, Millbank, London, S.W.1, price 6d.

An interesting Paris thesis by Dr. Albert Monnier (*Thèse de Paris*, 1937, No. 254) is devoted to the life and work of Jean Charcot, who followed his father as a neurologist for several years before he became an explorer.

Dr. Robert N. Nye has succeeded Dr. Walter P. Bowers as editor of the *New England Journal of Medicine* and Dr. Howard Fox has succeeded Dr. William Allen Pusey as editor of the *Archives of Dermatology and Syphilology*.

The King has appointed Dr. Arthur Hutton McShine, O.B.E., to be a member of the Executive Council of the Colony of Trinidad and Tobago.

The King has approved the appointment of Dr. Noel James Linnington Margetson to be an Official Member of the Legislative Council of the Presidency of Montserrat, Leeward Islands.

Dr. Max Neuburger, professor of medical history at Vienna, has been elected an honorary member of the American Association of the History of Medicine.

Dr. Georges Duhamel, member of the French Academy and editor of the *Mercure de France*, has been elected member of the French Academy of Medicine in place of the late Dr. Legendre.

The Bank of Rome has contributed a sum of 50,000 lire for the foundation of a Prince of Naples Institute for encephalitis to commemorate the birth of the son of the heir to the throne of Italy.

The New York banker Mr. W. Childs has left the University of Yale a sum of about 10 million dollars for cancer research.

A committee has been formed in Paris to erect a statue of Laennec in front of the Hôpital de la Charité, where he was physician.

A memorial to William and John Hunter was unveiled in East Kilbride Public Park on July 28 by Sir Hector J. W. Hetherington, principal of Glasgow University. It bears a relief symbolic carving with the inscription: "To the memory of William Hunter, M.D., F.R.S., 1718–1783, and John Hunter, F.R.S., 1728–1793. They were born at Long Calderwood, and died in London after attaining the highest eminence in the sciences of medicine and biology. Their names will be held in reverent remembrance by a grateful posterity to all generations."

Dr. Laubry has been nominated the first occupant of the new chair of cardiology in the Paris Faculty of Medicine.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
SECRETARY, *Medisecra Westcent, London.*
The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

B. coli Orchitis and Cystitis

"ANTIPODEAN" writes: A male, aged 30, had a severe left-sided orchitis, which developed into an abscess. The laboratory report showed principally *B. coli communis*. Five years later the same organism seemed responsible for a severe attack of cystitis. The patient is healthy in all other respects; the Wassermann reaction is negative; there is no history or evidence of tuberculosis; no constipation, rather the reverse: and the family diathesis is gouty. His habits are temperate and active. X-ray examination showed no calculi in the urinary tract or in the kidneys. The attack cleared up with mandelic acid, but we are puzzled as to the mode of entrance of the *B. coli*, first, to the testicle, and subsequently to the bladder. Can anyone explain this?

Thyroid Treatment of Lymphadenoid Goitre

Dr. P. G. DOOLEY (Co. Waterford) writes: Is it safe to administer thyroid extract, and if so, in what dosage, in a case of lymphadenoid goitre (Reidel's disease) in a female aged 70? Is the size of the gland likely to be influenced in respect of symptoms of dysphagia and dyspnoea? A short course of iodine appeared to aggravate the condition.

Sun Sensitivity

Dr. W. J. BURNS SELKIRK, in reply to "F. L." (*Journal*, July 3, p. 48), writes: In the *Archives of Pediatrics*, Sec. 1,935, pp. 833 to 840, he will find a very interesting communication by Dr. Eder on the administration of iron for such a case, even though the haemoglobin level is high. I have tried it in my daughter's case apparently with good results. Dr. Eder found similar benefit in children who blistered under ultra-violet rays, and he claims that if it is started early it prevents freckling.

Otitis Externa from Swimming Pools

Dr. R. S. GILCHRIST (Doncaster) writes: I wonder if any of your readers have had experience of the treatment and prevention of otitis externa resulting from swimming in pools of chlorinated water. I used to be a "daily dipper" until recently I developed this annoying condition, which begins as a sensation of fluid in the ear passage, with intolerable itching. Within a day or two there is a profuse discharge of serum, and pieces of desquamated epithelium—on one occasion a complete cast of the external ear passage—come away with this discharge. The condition may last for weeks, and even after it has apparently gone about a dozen dips in the pool bring it back again. I have tried rubber ear-plugs, vaseline, and cotton-wool, and a special submarine bathing cap, but none of these keep water out of the ear. For the ear itself ung. hydrarg. nitrat. dil., 5i in

3i liq. paraff., seems to be about the only treatment, and the results from this are extremely slow. Using a stethoscope while the condition is present is both difficult and unpleasant. Avoidance of swimming altogether cuts out one of life's few pleasures. I should be grateful for any advice on treatment and prevention that anyone can offer.

Parathyroid Extract and Enlarged Prostate

Mr. A. P. BERTWISTLE (London, W.1) writes: Can any reader tell me what is the action of parthyroid extract in the treatment of enlarged prostate? I have a patient, aged 78, in whose case cystotomy alone was possible, owing to a high blood urea. The man was going from bad to worse. At times the cystotomy wound closed, and he was in pain; he was becoming very sore, and his morale was rapidly sinking. Under the exhibition of parathyroid extract, grain 1/2, the patient improved at once, the cystotomy closed, and he has been at work for the last four months. I am grateful to Dr. Wood of Guernsey for recommending this line of treatment, which, he says, he used to adopt as a routine with excellent results.

Income Tax

Residence in United Kingdom

"JERSEY RESIDENT" has a total income of £2,500, £857 of which is from a pension. He inquires what income tax will be payable if he becomes a resident in this country.

*** The computation is as follows:

			£ s. d.
Total income			2,500 0 0
Deduct: Personal Allowance	£180		
Child Relief, £60 × 2 ..	£120		
Earned Income Relief, one-fifth of £857	£171		471 0 0
			2,029 0 0
Tax chargeable on £135 at 1s. 8d.			11 7 8
„ „ „ £1,894 at 5s.			473 10 0
	£2,029		484 17 8

This amount has to be compared with the present payment of £253 10s. United Kingdom tax and £40 Jersey tax. In addition surtax would be payable on £500—that is, £27 10s. There would be some relief in respect of Dominion income tax, but the above figures would not be substantially affected.

LETTERS, NOTES, ETC.

Blood Changes in Rheumatism

Dr. A. A. COCKAYNE (Christchurch, Hants) writes: In 1928 Tertius Clarke (*Proc. Roy. Soc. Med.*, **21**, 1004) suggested that rheumatic fever might be due to a protozoon attacking the red blood corpuscles. Examination of fresh unstained blood on a number of occasions during attacks of muscular rheumatism in myself and seven other people has yielded an appearance of some of the red corpuscles which might be due to a protozoon. On examination of a drop of fresh blood a few hours before and during an attack of pain some of the red corpuscles lose their disk shape, becoming globular and exhibiting projections which make them look not unlike the seed-case of the horse-chestnut. When fixed and stained with methylene-blue the projections disappear and there is simply a deeply stained sphere. In the fresh specimen one occasionally sees larger spherical cells containing a number of greenish star-shaped bodies. On one occasion there was a cell undergoing division into segments like an orange, each segment having a shiny black nucleus, rectangular in shape; on another occasion one of the horse-chestnut-like cells seemed to exhibit active amoeboid movement. Quinine seems to clear these cells from the blood in a few hours, together with most of the pain of the rheumatic attack, and to have a definite value in prolonging the intervals between attacks. Neither atebrin nor plasmoquine has been tried, though in theory they also might be efficient against a protozoon.

Termitary Turrets

Dr. WINIFRED COPPARD writes: In the *Journal* of July 17 (p. 118) you reviewed my translation from the Afrikaans of Eugène N. Marais's book *The Soul of the White Ant*. In developing his thrilling theory of the unity of the termitary and its similarity to the human organism, Marais mentions the development of abnormal growths in the "skin" of the termitary, which take the form of useless turrets. These turrets are a hindrance to the health of the organism as a whole, but are continually rebuilt as fast as they are destroyed by wind or weather. They are, in fact, analogous to malignant growths in the human body. Is it not possible that a study of the termitary, which, as Marais points out, is not a heap of dead earth, but a separate animal at a certain stage of development, may provide a clue to the functioning of the healthy human body, and perhaps even a solution to the problem of abnormal growths?

Moukden Medical College

In 1882 Dr. Dugald Christie, the pioneer medical missionary of Manchuria, landed at Newchang and made his way to Moukden. He was unable at first to found a medical centre there owing to intense local hostility, but in 1887 a hospital was opened, and five years later he started to train his assistants in scientific medicine. In 1907 a new and improved hospital was opened, and in 1909 a scheme was launched in Scotland to establish a Christian medical college there. After many vicissitudes the present establishment was brought into being in March, 1912, and the completion of twenty-five years of effective training since then has now been signalized by the publication of an illustrated pamphlet which combines an account of the work in Moukden with an appeal for funds as a memorial to the devoted founder, who died last December. Prominent events in the history of Moukden College include the graduation in 1917 of the first group of medical students after their five years' course of training; the initiation in 1919 of a medical journal in Chinese; the admission of the first women students in 1924; the addition in 1931 of a complete new story to the College teaching block to accommodate classrooms, laboratories, museums, and library; the recognition of the College in 1931 also as the medical faculty of the local university, and in 1934 its recognition by the University of Edinburgh for the admission of its students to post-graduate courses and examinations for Scottish diplomas; and in 1935 the receipt by this institution of the first of a series of grants from the Boxer Indemnity Committee. At present the College is recognized by the Government of Manchoukuo and the University of Edinburgh for certain postgraduate diplomas. The language of instruction is Chinese, but Japanese and English are also taught. About twenty new students are admitted each year to the seven-year course, which is modelled on Scottish University standards. The Church of Scotland Mission Hospital, which is adjacent, has 300 beds, with departments of surgery, internal medicine, tuberculosis, paediatrics, ophthalmology, dermatology and venereal diseases, oto-rhino-laryngology, gynaecology and ante-natal work, and radiology; 5,000 in-patients are treated each year, and there are 120,000 out-patients. Despite the disturbed conditions in the country since its inauguration the College has forged its way ahead. It is proposed to establish a Christie Memorial Chair. Further information may be had from Dr. H. S. D. Garven, Greyfriars, Barnshot Road, Colinton, Edinburgh.

A Warning

Dr. ALICE GILBY (London, S.W.1) writes: A man recently called on me answering to the following description. He was tall but rather bent, and had strikingly pale blue eyes, deformed hands (apparently due to rheumatoid arthritis), and a queer (?) Oxford accent. He is 60 to 70 years old, and shabbily dressed. He claims to be a Dr. Stewart, and says he used to practise in Ebury Street, S.W.1, and was struck off the Register recently for carelessness in dispensing medicine, which led to the death of a patient. He asked for work as a dispenser or assistant. He says he is trying to get back on the Register, and showed a letter purporting to come from his solicitor referring to this and informing him that references would be required before he could appeal for reinstatement. The letter is dated June 9, 1937. When he found I did not fall for the dispenser idea he asked me point blank for money. He claims also to have worked recently for a dental surgeon.

*** We are informed by the dental surgeon that a man calling himself Dr. Stewart on one occasion and Dr. Robinson on another was given money by him, but that he has not employed him.

An interesting pamphlet on the indications for and the therapeutic uses of infra-red rays has just been published by Messrs. Hanovia Ltd., the makers of sollux lamps. The physics and physiology of infra-red radiation are dealt with and the many uses to which the sollux lamps can be put are considered. The booklet may be obtained on application to the makers at their showrooms, 3, Victoria Street, S.W.1.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

149 Sclerodermal Dystrophies

H. CURSCHMANN (*Med. Welt*, July 3, 1937, p. 925) prefers to consider sclerodermia as one symptom in a clinical picture presenting many others, and to term the whole "sclerodermal dystrophy." In sclerodermia pluriglandular disturbances are common. Curschmann describes cases of dysfunction of the thyroid, the testis, the ovary, the anterior pituitary, and the adrenals, all of which occurred with sclerodermal skin conditions, and in addition allergic factors were often contributory causes. Eosinophilia was found, accompanied by secondary anaemia in many cases, and the author describes one case of sclerodermia co-existent with pernicious anaemia. In another he found that a true C-avitaminosis not only produced scorbutic skin haemorrhages but also generalized pigmentation and a typical sclerodermia. He points out that in sclerodermia scurvy should be looked for and the urine tested for ascorbic acid before and after the administration of vitamin C. Treatment of the secondary skin changes is then more likely to be effective. He advocates a trial of vitamin therapy in other cases of this condition, as most forms of treatment, especially in chronic and dystrophic cases, have hitherto been ineffective.

150 Undulant Fever

G. OLIN (*Hygiea*, Stockh., June 15, 1937, p. 401) gives an account of the behaviour of undulant fever in Sweden, where it is caused only by *Brucella abortus*, *B. melitensis* and *B. suis* playing no important part in this country. The geographical distribution of the 1,121 cases of undulant fever notified in the period from 1929 to 1936 corresponded to that of infectious abortion in cattle, but while the latter exists in at least 10 per cent. of all the herds and serological tests have suggested that some 33 per cent. are infected, the incidence of undulant fever in man in the period under review was only 2.04 a year per 100,000 inhabitants. The comparative immunity enjoyed by man was traced by the author to the feebly pathogenic properties of *B. abortus* so far as human beings are concerned. Yet, when they fell ill, the average duration of the fever in 115 cases was over ninety-one days, varying from 8 to 532 days. The post-febrile pediod of convalescence was also long, being usually about three months. In all the illness commonly lasted six months, but a fatal issue occurred in only 2.2 per cent. of cases. The author considers that fully three-quarters of all the Swedish cases were due to milk infections and not to direct contact. He foresees in the extension of milk pasteurization the most effective preventive of undulant fever. Of the benefits of prophylactic inoculation he is more doubtful, although it may be advisable for those who are especially exposed to contact infections. His skin tests on 293 persons with an antigen have convinced him that a good proportion of the community undergo infection unwittingly and without any noticeable clinical reaction.

151 Late Effects of Tetanus

O. SPRENGER (*Zbl. inn. Med.*, June 5, 1937, p. 481) states that after recovery from tetanus skeletal or other bony deformities, as well as muscular rigidity or contractures, have occasionally been noted. The occurrence of convulsions as a late effect is rare. The case is reported of a barber, aged 20, who had recovered four years previously from acute tetanus, which had set in four days after a wound of the right thumb. Although he was following his profession, he was found to exhibit chronic extensor convulsions of the legs and buttocks on stimulation of the skin or joints of the lower extremities, and of the arms on deep pressure on the internal bicipital sulcus. Spontaneous convulsions very rarely occurred—a point against the alternative diagnoses of cramp-neurosis, chronic tetanus, or a psychogenic functional syndrome. The blood urea was normal. Sprenger believes that the very thorough intraspinal serum injections, carried out in the acute stage and followed by a notable pleocytosis in the liquor, were responsible for the later convulsions. The patient showed notable intensification of the pyramidal tract reflexes.

152 Acute Eosinophilic Leukaemia

C. E. FORKNER, C. T. TENG, Y. C. C'HU, and W. COCHRANE (*Chin. med. J.*, May, 1937, p. 609) record a case of acute eosinophilic leukaemia, which they claim to be the fifth recorded in the literature. The patient was a male Chinese police officer aged 33. His illness lasted for twenty-seven days, and ended fatally. The main findings were as follows. (1) There was restlessness and mental cloudiness; (2) the neck was rigid; (3) the left plantar reflex was extensor, but the right was doubtful; (4) the superficial lymph nodes were enlarged; (5) purpura was present; (6) there was leukaemic retinitis; (7) the gums were hypertrophied; (8) the uvula and pharynx were ulcerated; (9) blood pressure was low—88/54 mm. Hg—and there was Cheyne-Stokes respiration; and (10) the liver and spleen were enlarged. A blood examination made three days before death showed red blood cells 3,890,000, haemoglobin 11.8 per cent., and white blood cells 265,000, of which 81 per cent. were eosinophils. The platelets were much reduced in number, and the cerebrospinal fluid contained segmented eosinophils and eosinophilic myelocytes. No parasites or ova were found in the faeces when examined on five occasions. Towards the end the patient developed pneumonic symptoms. No post-mortem examination was made.

Surgery

153 Fertility after Vasectomy

H. KNAUS (*Zbl. Chir.*, June 26, 1937, p. 1506) draws attention to the experimentally established fact that spermatozoa only remain fertile for a few days when submitted to the temperature of the abdominal cavity, whereas fertility lasts as long as forty days in the epididymus owing to the relatively lower temperature of the scrotum. There is a difference of from 2.7° C. to 7.8° C. between the temperature of the scrotum and that of the abdominal cavity. The cause of the death of the spermatozoa in the seminal vesicles is their accelerated mobility, which exhausts their potential energies. Therefore, when the vas is resected with the object of sterilization, this should be done outside the scrotum. In this way spermatozoa retained in the seminal ducts will be sterile by the time the operative wound has healed.

154 Lymphangiomata

A. O. SINGLETON (*Ann. Surg.*, June, 1937, p. 952) divides lymphangiomata into three types: simple or capillary, cavernous, and cystic. The first of these occurs superficially, and is easily diagnosed and removed. Cavernous lymphangiomata consist of a framework of connective tissues in which there are numerous single and communicating lymphatic cysts. There are also many anastomosing channels, irregular masses of lymphocytes, lymph nodes, and lymph follicles. These tumours are found in the neck, axilla, and groin, and may be so extensive that their removal necessitates major operation. Cystic lymphangiomata are tumours with larger, thin-walled, convoluted cysts filled with lymph and lymphatic fluid. They

are commonly found in the neck, and may be present for some time before they enlarge. Lymphangiomata may be found in any part of the body; the most formidable are those within the abdomen, both retroperitoneally within the mesentery of the intestines and in the omentum. In these cases intestinal obstruction is a common complication. Because of the dysfunction of the lymphatic chain infection is a serious development as it spreads rapidly through the connecting cysts. There are also communications between the cysts and venous radicles, and a blood-stream infection may develop. Excision is the usual method of treatment, and it may be difficult owing to the extent of the process. Radiation, either alone or in conjunction with surgery, is of value. Details are given of twenty-eight cases; operative treatment was carried out in all but two instances, in which radiotherapy alone was applied. In nearly every case recovery took place, and there was a very low percentage of recurrence.

155 Chronic Appendicitis

J. LE SAGE (*Union méd. Can.*, June, 1937, p. 601) distinguishes between the two types of chronic recurrent appendicitis, one of which follows an acute attack while the other is chronic from the onset. In the first case surgical intervention should be carried out, but in the second, medical treatment should first be tried. A case is reported in which the patient had suffered from symptoms of asthenia accompanied by amnesia, with eructation, and other digestive disorders for ten years. Symptoms were most pronounced after meals and were relieved by purging. In addition, the man had had attacks of vertigo, sweating, and biting of the tongue. He was a large eater, a hard worker, and a heavy cigar smoker. The patient remembered that he had had acute indigestion and colic at the age of 15. On examination the abdomen was distended, notably in the right hypochondrium; there was also a small umbilical hernia. A diagnosis of intestinal stasis was made, with pluriglandular insufficiency as a result of intestinal toxaemia. Adrenaline, mucilage, and milk of magnesia were given, but the constipation persisted. As the patient's condition did not improve, a bismuth meal was given, and this showed evidence of appendicitis, with a fixed retrocaecal appendix. Operation was carried out, and the caecum and the appendix were found to be bound down with adhesions. The omentum, which was also fixed by adhesions to the anterior abdominal wall, was freed. The general condition improved, the digestive function soon became normal, and the epileptiform syndrome disappeared.

156 Late Effects of Infantile Coxitis

S. C. IVERSEN (*Hospitalstidende*, June 8, 1937, p. 629) has examined sixteen children and thirteen adults who had suffered from an apparently non-specific coxitis characterized by pain, fever, swelling, and fixation of the hip, usually accompanied by abscess formation, during the first year of life. The examination of these patients many years after the onset of their disease revealed profound anatomical and radiological changes, with corresponding deformities and functional disturbances; the movements about the hip were seriously impaired. All the patients limped as a result of shortening of the affected limb, dislocation at the hip, limited range of movement, ankyloses, contractures, weakness of certain muscles, or secondary changes in the knee, ankle, or other joints. To a shortening of 2 to 4 cm. about the joint itself could be added the shortening due to adduction and atrophy of the femur, so that in several cases there was an effective shortening of as much as 9 cm. In as many as twenty-two cases the hip was dislocated, the great trochanter resting against the iliac crest. These patients were in a worse condition than the subjects of congenital dislocation of the hip, whose gait closely resembles theirs. In spite of their deformities they were able to lead an active life, and some could bicycle and skate. The dominating disturbance in adults was pain, and they all complained of this. It radiated down the leg, but seldom to the back, as is the case with congenital dislocation of the hip. The author's remedies include early operative intervention, with incision of abscesses and the readjustment of the head of the femur in infancy.

Therapeutics

157 Barbiturate Poisoning

COUBRIN and SOUBIRAN (*J. Méd. Bordeaux*, June 5, 1937, p. 746) point out that in barbiturate poisoning the bulbar effect is more important than that on the higher centres. It occurs about six hours after the ingestion of 5 to 6 grammes. Respiration is superficial, and the pulse, while regular, becomes almost imperceptible. The heart is affected by the direct toxic action on the myocardium, its nerves, and their centres, and indirectly by the deficient respiration. It is necessary to maintain respiratory function by mechanical means, and in this respect Cot's apparatus is superior to manual or medicinal methods. The administration of carbon dioxide is a valuable adjuvant. There is no doubt that continued artificial respiration reacts favourably on the heart and pulse, but in all cases care must be taken to maintain body heat.

158 Tuberculous Diabetics

E. MELZER (*Dtsch. Tuber.-bl.*, July, 1937, p. 161) has treated a number of diabetic tuberculous patients with insulin, and comes to the conclusion that the patients respond fairly well to this therapy provided they are given a liberal diet. The treatment thus applied improves the general condition of the patient, and also the condition of the lungs. According to the author it would be wrong to apply a strict diabetic diet in such cases. On the contrary, the diet must approach as nearly as possible to the normal, while the doses of insulin should be kept high. Only in this way is it possible to achieve success in cases which were considered hopeless before the insulin era.

159 Pulmonary Tuberculosis

O. LASSEN (*Ugeskr. Laeg.*, June 10, 1937, p. 615) has undertaken an intensive study of the clinical histories of the last 100 patients who died of open pulmonary tuberculosis in the town of Aarhus, Denmark. The average age at death was between 31 and 32, and two-thirds were under 35. The clinical and radiological reports at the time when the diagnosis was first made showed in as many as seventy-eight cases such advanced disease that little hope of recovery could be entertained; and among the remaining twenty-two cases advanced, but still curable, disease was often found. A study of the institutional careers of these 100 patients revealed that as the disease progressed the duration of hospital or sanatorium treatment became longer, and as all the cases terminated fatally no permanent benefit could be claimed on their behalf for the institutional treatment they had received. Did it benefit the community by the limitations it imposed on opportunities for spreading the disease? The author is inclined to think that these patients did all the harm they could in this respect while they were still leading free and active lives. In Aarhus 82 per cent. of all the deaths from tuberculosis take place in hospital, and though this arrangement certainly ensures that the patients receive good nursing, the author wonders how valuable it is from the epidemiological point of view. He notes in this connexion that while the tuberculosis mortality has recently declined in a most encouraging fashion, there is not a corresponding decline in the tuberculosis morbidity.

Anaesthesia

160 Oral Intubation

W. S. SYKES (*Anesth. and Analges.*, May–June, 1937, p. 133) describes a simple method of tracheal intubation which he claims has many advantages over those which at present are most commonly used—*namely*, *Magill's* blind nasal method and oral intubation through a direct vision laryngoscope. His tube is a modification of "Kuhn's tube"; it is made of rubber with a central fenestrated point at the tip, the proximal part is stiffened by a wire coil and terminates in an adapter, by means of which it can be connected to an ether vaporizer or gas machine. For introduction it is mounted on a curved metal introducer similar to Kuhn's. The patient is deeply anaesthetized and the mouth gagged open. The anaesthetist stands on the patient's right, hooks up the tongue and epiglottis with the first two fingers of the left hand, and then slides the tube on its introducer along the posterior surface of the epiglottis and so without trauma into the larynx. The procedure is completed by connecting the machine and packing gauze round the tube in the pharynx.

161 Intravenous Scopolamine-eukodal-ephetonin

PHILIPPIDES (*Schmerz Narkose-anaesth.*, June, 1937, p. 39) states that the properties of scopolamine render it peculiarly valuable as a hypnotic and analgesic; it inhibits the parasympathetic and so, like atropine, it decreases the tone and motility of smooth muscle and the activity of the glands, while in contrast with the latter it depresses both the motor and sensory centres of the central nervous system. When combined with a morphine preparation, such as eukodal, a powerful analgesic effect is obtained, but is often accompanied by undesirable depression of circulation and respiration. These effects are its chief drawbacks, together with the liability to individual variation in response when it is given hypodermically in one dose. The addition of adrenaline has a detoxicating effect, and Merck's "weak scopolamine solution," which the author recommends, contains in each cubic centimetre about 1/130 grain scopolamine, 1/6 grain eukodal, and 1/3 grain ephetonin, which has a more lasting effect than adrenaline. Accurate individual dosage is ensured by slow intravenous injection, which is stopped when the patient feels comfortably tired; a complete twilight sleep is not aimed at, but self-control is maintained and patients are able to co-operate. Usually less than 1 c.cm. injected in from one to one and a half minutes is needed; resistant cases may require more than this amount, and caution must be observed in poor risks. The injection usually causes a rise in blood pressure of from 15 to 20 mm. Hg, and an increase in the pulse rate of from 20 to 30. The dose may be repeated in one to one and a half hours, as its effect wears off. The method is particularly recommended as an adjuvant to local and spinal analgesia, and for the rapid relief of severe pain of any kind, notably renal, gall-stone, or other colic. It is also preferable to morphine and atropine as a preliminary to general anaesthesia, and it may also be used before intravenous evipan.

162 Blood Sugar Variations

A. ATNAN and E. FENZ (*Wien. Arch. inn. Med.*, June 30, 1937, p. 301) have investigated the influence of ether, evipan, and spinal anaesthesia on the blood sugar. They found that it showed a much greater increase during and after ether anaesthesia than after spinal anaesthesia. The increase was independent of the amount of percaine injected and of the level of the spinal injection, but the blood sugar remained higher for six hours after spinal anaesthesia as compared with twenty-four hours after ether anaesthesia. The increase was less in a case of mild diabetes for both ether and spinal anaesthesia. This investigation seems to prove that spinal anaesthesia is not contraindicated in diabetes.

163 Anaesthesia and Maternal Mortality

T. L. MONTGOMERY (*J. Amer. med. Ass.*, May 15, 1937, p. 1679) is concerned at the large number of maternal deaths associated with anaesthesia, and has investigated the maternal mortality in Philadelphia during the period 1931 to 1935. He has published statistics covering 155,133 live births and 1,096 maternal deaths, which show that there has been a general improvement except in the case of deaths occurring during labour or within twenty-four hours of it, while the number of maternal deaths attributed to errors on the part of the physician have increased by over 100 per cent. The author holds that an important cause of mismanagement lies in the method of analgesia, anaesthesia, or amnesia, and he gives warning against the too ready adoption of methods which have received wide publicity through enthusiastic articles in the lay or medical press. Safety is the most important factor, and he entirely condemns spinal anaesthesia on account of its high mortality in obstetrics. He considers the barbiturates more dangerous than is often claimed, and they are also uncertain and may be troublesome. His experience of chloroform is very limited, but he points out its dangers in pre-eclampsia. Ether appears to be the safest anaesthetic, but should not be given too freely or for too long. In the form of Gwathmey's oil–ether it can be very useful. Gas-oxygen is of value and does not interfere with uterine contractions, but it should not be given when relaxation of the muscle is needed. The author makes a strong plea for the greater use of local anaesthesia with 1/2 per cent. novocain, both for Caesarean section and for infiltration of the perineum during delivery. He emphasizes the fact that patients should not be promised any routine form of pain relief, but that each case should be dealt with individually at the onset of labour.

164 Spinal Anaesthesia in Gynaecology and Obstetrics

R. MEYLAN (*Gynéc et Obstét.*, May, 1937, p. 339) has used spinal anaesthesia in 220 of the 1,069 gynaecological operations performed in the Geneva Women's Hospital from 1930 to 1934. Owing to technical difficulties and the lack of expert anaesthetists he has abandoned percaine, and now uses "syncaine" crystals, which are dissolved in the cerebrospinal fluid and reinjected with the patient in the sitting position in the third or fourth lumbar space. Anaesthesia is complete as soon as the patient has been placed horizontal and prepared for operation. The author stresses the importance of comfort on the table, and of the part played by the assistant, who supervises the patient, in maintaining morale. An injection of pantopon and atropine is given three-quarters of an hour before, and blood pressure is kept up by preliminary injections of ephedrine or cardiazol–ephedrine, repeated if necessary. The inhalation of carbon dioxide–oxygen mixtures is often used for treating nausea, etc., with success. Of the 200 cases in which "syncaine" was administered seventy-seven gave perfect results, in seventy-eight anaesthesia was adequate though incomplete, and in forty-five some supplementary inhalation anaesthetic was required. The results were particularly favourable in vaginal operations. The author ascribes some of the failures to Sebrechts's "rachi-resistance." Encouraged by his success in gynaecology, the author has used spinal anaesthesia in 100 obstetric operations, of which fifty-nine were Caesarean sections; in all, there were sixty good results, thirty-one poor but adequate, and nine failures. In general the results obtained in obstetrics were better than in gynaecology, and smaller doses could be employed. The author observes the usual contra-

indications, and in obstetrics advises particular caution in the presence of haemorrhage or shock; he regards cardiovascular disease as a complete contraindication. The method is essentially indicated in Caesarean section, which is rendered almost bloodless by the early and complete uterine retraction, which may, however, render internal version difficult. In Caesarean section and hysterectomy the anus should be well plugged to prevent the soiling of the vulva through the active peristalsis which occurs. The relaxation of the cervix and of the perineal and pelvic muscles renders forceps delivery easy, but owing to the danger of a complete rupture of the perineum the author does a wide lateral episiotomy as a routine. The most troublesome complication was headache of a few days' duration, which was resistant to treatment. One death occurred among the 300 cases, from septic meningitis following the lumbar puncture; of the other nineteen fatalities none could be ascribed in any way to the anaesthesia.

Obstetrics and Gynaecology

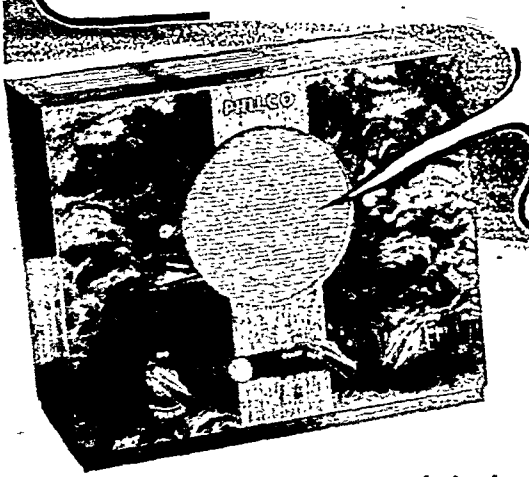
165 Athmocausis for Uterine Haemorrhage

J. A. SCHOCKAERT (*Brux. méd.*, May 23, 1937, p. 1091) discusses the various methods of treatment, including hormone therapy, surgery, and radiotherapy, which may be used in cases of uterine haemorrhage. Athmocausis, which consists of the destruction of the endometrium by the passage of steam, is a further method of treatment valuable in women before the menopause. By this means amenorrhoea is produced without affecting the internal ovarian secretion. The process and apparatus are fully described, and the results, which were mostly satisfactory, of forty-five cases treated by this method are given. The majority of patients were between the ages of 30 and 45, and fifteen were under forty. In order to obtain the best result the treatment must continue for three and a half to four and a half minutes; cases which were treated for a shorter period were liable to recurrence. A total of seventy patients were treated without any untoward consequences. Care was always taken to treat the fundus of the uterus for a longer time than the neck in order to avoid an accumulation of blood behind a cervical stenosis. Athmocausis of short duration is indicated in cases of uterine haemorrhage in young persons when curetting and hormone therapy have proved unsuccessful and hysterectomy is inadvisable. In most cases treatment for four to four and a half minutes is required for the destruction of the uterine mucosa in order to cure pre-menopausal or menopausal haemorrhage. This should be carried out in patients over thirty-five years of age. Contraindications are inflammatory conditions of the uterus and adnexa, endometritis, haemorrhage caused by retention of the placenta, and uterine fibromata.

166 Unilateral Absence of the Adnexa

P. CAFFIER (*Zbl. Gynäk.*, June 26, 1937, p. 1506) records the case of an unmarried woman, aged 23, in whom laparotomy for fixed retroversion of the uterus revealed absence of the right ovary and of the right Fallopian tube, except for a button-shaped thickening at the site of the uterine insertion. He remarks that unilateral absence of the adnexa has always been a riddle, and points out that if the criteria of Kermauner be adopted—namely, the absence of one side of the ovary, Fallopian tube, half the uterus, round ligament, and inguinal canal, as well as the kidney and ureter—only six cases at the most of congenital non-development have been recorded. In all others the uterus has not been of the unicornis type. Twelve well-authenticated cases similar to Caffier's have been described, in half of which, however, 1 to 1.5 cm. of the internal end of the tube was present. It is probable that some of them have been due to past pelvic inflammation or past acute torsion and detachment, the clinical features having then been confused with typhoid, appendicitis, etc.; clear signs of tubo-ovarian amputation by torsion have been found at necropsy in young children. From such considerations and from the fact that careful search has sometimes revealed in the omentum or elsewhere microscopical signs of ovarian tissue embedded in scar in cases in which the adnexa had apparently been absent on one side, Caffier agrees that congenital absence is of the utmost rarity, and that the disappearance may take place during foetal life. Compensatory enlargement of the other ovary has been noted in several cases; the majority show cystic or inflammatory disease on the other side. The defect is by no means a cause of sterility provided that the remaining ovary remains healthy. Three out of sixteen cases had contralateral dermoids, but few had menstrual abnormalities, although usually puberty occurred late. The cases in question afford no evidence as to the credibility of the theory which would explain the birth of males or females as due to the fertilization of ova from the respective sides; and this is in accordance with Caffier's own experience of patients on whom he has performed unilateral oophorectomy.

Pathology



167 Opsonin Tests in Pertussis

P. KENDRICK, J. GIBBS, and M. SPRICK (*J. infect. Dis.*, May–June, 1937, p. 302) have studied the immunity problem in pertussis by immunizing children with a "phase I" *B. pertussis* antigen of 20 billion killed germs per c.cm. The progress was estimated by a special mode of numerical observation of the bacilli ingested in leucocytes in a citrated blood drop incubated with the antigen—a method more easily conducted than others in infants. The use of the opsonic index was not practicable by reason of the packing of the cells, and a modified "opsonocytophagic" count was done. A progressive increase of opsonins was noted during immunization. The reaction decreased after six months and became perceptibly weaker after two years, although up to the age of 18 months a negative response is usual in those with no history of an attack. It is hoped that the method may be of value in studying vaccine dosage and potency. During the attack the opsonocytophagic test does not become positive early enough to be of general diagnostic value.

168 Nutritive Value of Boiled Milk

S. GRAHAM and N. MORRIS (*Arch. Dis. Childh.*, June, 1937, p. 169), in order to decide whether or not sterilization altered the biological value of milk, gave two children a diet in which 50 per cent. of the calorific value and 70 per cent. of the total protein were supplied in the form of milk. The calorific intake as well as that of proteins, minerals, and fats, were ample. Milk from the same source was utilized throughout the investigations. All the milk given to one child was boiled for three minutes. Urine and faeces were collected for seven days after the diet had been given over a period of not less than five days. Thereafter, in one case the milk was changed from raw to boiled, and in the other from boiled to raw. This was continued for a fortnight, and the two cases were then given their original variety of milk for another fortnight. The results of these analyses are given in tables, and indicate that there is no evidence that the boiling of milk over short periods impairs either its absorption or utilization when the calorific intake is adequate. It is still possible that over long periods, when the intake is no more than sufficient, the sterilization of milk might make a difference to its nutritive value, but no proof of this has been forthcoming.

PHILCO designed me to serve every Medical Man in the country!

PHILCOPHONE—

the most modern internal communication system

No more wasted steps; no more irritating waits; no more straining to catch words on an old-fashioned house-telephone!
Here is the Philcophone . . . far more than a house-telephone!

The Philcophone gives you instant and private two-way communication between a Master Control Unit and one or more Remote Units in other portions of the building. Your conversations can be carried on in any volume you desire: the microphone-loudspeaker picks up your normal speaking voice wherever you may be in the room, and relays it at whatever strength you choose.

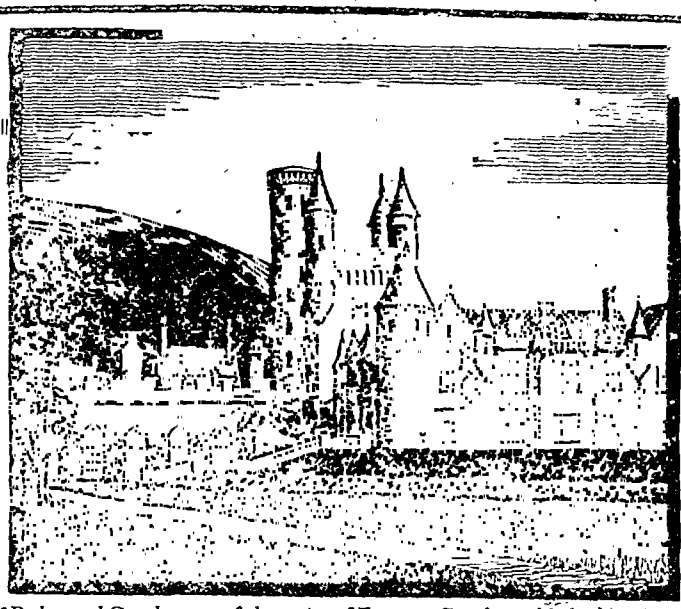
The Philcophone is built of Philco standard parts. It gives Philco high performance on either A.C. or D.C. Mains, and can be installed with little cost and no bother. The Master Control Unit has a cabinet of walnut, with a knob to control the volume. A red light shows when the system is in operation.

The Master Control and one Remote Unit cost only . . . **12 GNS**

Each additional Station 2 gns. extra.

THE PHILCOPHONE CAN BE BOUGHT FOR AS LITTLE AS 23/6 A MONTH

GIVES YOU MORE THAN A HOUSE-TELEPHONE . . . COSTS YOU FAR LESS



PHILCO RADIO & TELEVISION CORPORATION OF GREAT BRITAIN, LTD., PERIVALE, GREENFORD, MIDDLESEX

Please send me, without obligation, complete particulars of the PHILCO-PHONE.

for RELIABILITY

'CELLANBAND'

ANTISEPTIC PASTE-IMPREGNATED

BANDAGES

The CELLANBAND Dressing, when properly applied, furnishes a mechanical support vastly superior to crepe or rubber bandages, elastic hosiery, etc., and will usually be found sufficiently robust to enable the convalescent to resume reasonable light duties at an earlier period. CELLANBAND Dressings exercise a marked dehydrating and antiphlogistic effect, resulting in rapid reduction of oedema. Air-access to the tissues is not interfered with as in the case of gelatine dressings, so that evaporation of the skin secretions continues normally.

12/- PER DOZ. (7 yds. long, 4 in. wide)

SAMPLE BANDAGE **1/-** POST FREE

'SANOID'

STERILIZED LIGATURES

These ligatures are British both in production and materials. Their Tensile strength is well in excess of the recognised standards for particular sizes. A special process gives a surface-finish that ensures easy manipulation. SANOID Ligatures are exceedingly supple; the catgut straightens out and remains straight without "kinks" which are liable to cause breakage. Sterilization is carried out by the most up-to-date methods, and independent Bacteriological tests over several months in all cases gave negative results. Exceptional elasticity lessens the risk of necrosis.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS
NORTHAMPTON.
FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen at London by appointment.

Apply, SECRETARY, Medical Correspondence College, 19, Welbeck Street, W.1.
Free booklet "The M.R.C.P. and How to Obtain It" on application.

LONDON HOSPITAL MEDICAL COLLEGE AND DENTAL SCHOOL

THE WINTER SESSION will open on FRIDAY, OCTOBER 1st.

The London Hospital serves the East End of London, and with eight hundred and fifty beds is the largest voluntary Hospital in England. The Out-patient Department, which deals with a hundred thousand new patients per annum, is extensively used for teaching.

The size of the Hospital necessitates a large number of resident medical officers. Every year seventy resident house physicians and house surgeons and eighty salaried non-resident clinical assistants are appointed from among recently qualified students. The opportunities which these appointments offer for obtaining clinical experience are invaluable.

The Medical College is attached to the Hospital and is staffed by Professors of Anatomy, Physiology, Bacteriology, Chemical Pathology, Morbid Anatomy and Medicine of the University of London.

Special Courses in Anatomy and Physiology for the Primary F.R.C.S. and advanced courses in Surgery for the Final F.R.C.S. Examination, and in Medicine for the M.D. and M.R.C.P. Examinations, are held twice a year.

Entrance Scholarships and prizes of the total value of £950 are awarded annually. Research Funds to the value of £113,000 permit of assistance being given to students and graduates engaged in medical research.

The Medical College contains a modern Museum of Pathology and a Library provided with all the current medical periodicals in charge of a full-time librarian. There is also an Athenæum Club and Dining Hall, a Gymnasium, a Fives Court, and two Squash Courts in the Students' Hostel. The Athletic Ground of 13 acres at Hale End is within easy distance of the Hospital.

The Hospital is only 20 minutes from Charing Cross and Baker Street Stations. For those who wish to live in immediate proximity to the Hospital there is accommodation for sixty students in the Students' Hostel.

Further details may be obtained from the Dean, Dr. A. E. Clark-Kennedy, M.D., F.R.C.P., Physician to the Hospital and Fellow of Corpus Christi College, Cambridge, who is always pleased to meet students wishing to see the Hospital and College and to whom application for admission should be made.

Turner Street, London, E.1.

LONDON HOSPITAL MEDICAL COLLEGE

F.R.C.S.

A Course of Instruction for the FINAL FELLOWSHIP EXAMINATION will begin on Monday, August 30th, 1937. Fees (exclusive of Operative Surgery), 25 guineas. Operative Surgery, 10 guineas.

Further particulars may be obtained from:—Dr. A. E. CLARK-KENNEDY, M.D., F.R.C.P., Dean, London Hospital Medical College, Turner Street, London, E.1.

LONDON HOSPITAL MEDICAL COLLEGE

PRIMARY FELLOWSHIP EXAMINATION.

A COURSE OF INSTRUCTION for the above Examination will begin on Wednesday, Sept. 1st. The fee for the Course is 15 guineas.

Further particulars may be obtained from Dr. A. E. CLARK-KENNEDY, M.D., F.R.C.P., Dean, Turner Street, Mile End, E.1.

ADVICE ON THE CHOICE OF SUITABLE SCHOOLS AND TUTORS

Applications are invited for the post of JUNIOR ASSISTANT MEDICAL OFFICER (man or woman) at the Memorial Sanatorium, near Warwick, of 225 beds.

The salary will be at the rate of £250 per annum, with board, lodging and laundry in addition, and the successful candidate will be appointed for six months.

There are three other Medical Officers at the Sanatorium.

Applications, with copies of testimonials, should be forwarded *direct to the Medical Superintendent at the Sanatorium* to reach him by not later than Wednesday, August 25th, 1937.

Shire Hall, Warwick. L. EDGAR STEPHENS, Clerk of the Joint Committee.

August 7th, 1937.

CITY OF LEEDS.

ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified and registered Medical Practitioners for the post of Assistant Medical Officer for Maternity and Child Welfare. Applicants must have had not less than three years' post-graduate experience, including experience in General Medicine and Surgery, and special experience in Obstetrics and Ante-Natal work, and in the treatment of Children's Diseases and Diseases of Women. Preference will be given to candidates possessing the D.P.H.

The commencing salary for the post will be £500 per annum, and the present Grading Scheme of the Corporation provides for annual increments of £25, to a maximum of £700.

The person appointed will be required to pass a medical examination, and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922. The appointment will be terminable by one month's notice on either side.

Form of application and particulars as to the duties of the appointment may be obtained from the undersigned.

Applications, endorsed "Maternity and Child Welfare Officer," together with copies of three recent testimonials, must be delivered at the Health Department, 12, Market Buildings, Vicar Lane, Leeds, 1, not later than 12 noon on Saturday, September 4th, 1937.

Canvassing in any form, either directly or indirectly, will be a disqualification.

J. JOHNSTONE JERVIS, Medical Officer of Health.

LANCASHIRE COUNTY COUNCIL.

Biddulph Grange Orthopaedic Hospital.

Applications are invited from duly qualified and registered Medical Practitioners (unmarried) for the post of JUNIOR HOUSE SURGEON at the above Hospital, which contains 88 beds.

Salary is at the rate of £200 per annum, together with board, residence and laundry.

Preference will be given to candidates who have held resident hospital appointments and who are competent anaesthetists. The appointment will be for a period of six months in the first instance, and for a further six months at the option of the Council, but will not be renewable after that time.

Applications, with copies of two recent testimonials, should be sent not later than September 4th, 1937, to Dr. F. HALL, School Medical and Child Welfare Department, County Offices, Preston.

Duties to commence October 1st, 1937.

County Offices, Preston. GEORGE ETHERTON, Clerk of the County Council.

August 16th, 1937.

BRITISH POSTGRADUATE MEDICAL SCHOOL.

Applications are invited for the post of RESIDENT ANAESTHETIST on the staff of the British Postgraduate Medical School at Hammersmith Hospital (L.C.C.), Ducane Road, W.12. The appointment will be for six months, to commence duty on October 1st, 1937.

Salary will be at the rate of £150 per annum, with board, lodging and laundry. Preference will be given to candidates who have held a similar appointment.

Further information can be obtained from the Dean, British Postgraduate Medical School, Ducane Road, W.12, to whom applications, accompanied by testimonials, should be sent, to arrive not later than first post on Monday, September 6th, 1937.

BRITISH POSTGRADUATE MEDICAL SCHOOL.

Applications are invited for the post of HOUSE SURGEON (Obstetrics) on the staff of the British Postgraduate Medical School at Hammersmith Hospital (L.C.C.), Ducane Road, W.12. The appointment will be for six months, to commence duty in September.

Salary will be at the rate of £105 per annum, with board, lodging and laundry.

Further information can be obtained from the Dean, British Postgraduate Medical School, Ducane Road, W.12, to whom application, accompanied by two testimonials, should be sent, to arrive not later than first post on August 26th, 1937.

BRITISH POSTGRADUATE MEDICAL SCHOOL.

Applications are invited from registered Medical Practitioners for the post of CASUALTY OFFICER, to commence duty on October 1st, 1937.

The appointment is for six months and non-resident. Salary is at the rate of £150 per annum and the post is specially suited to candidates studying for higher qualifications.

Applications, accompanied by two testimonials, should be addressed to the Dean, British Postgraduate Medical School, Ducane Road, W.12, to arrive not later than first post on Monday, September 6th.

AMENDED ADVERTISEMENT. SURREY COUNTY COUNCIL.

Surrey County Hospital, Wolverton Avenue, Kingston-upon-Thames. (550 Beds. Maternity Units 53 Beds.)

RESIDENT OBSTETRICIAN.

Applications are invited for the above whole-time appointment from registered medical practitioners who have had good experience in Obstetrics. Applicants must hold a higher qualification, e.g. F.R.C.S. or M.C.O.G.

The Hospital is approved by the Central Midwives' Board for the training of midwives and by the General Nursing Council as a full training school for general nursing.

The gross salary will be at the rate of £725 per annum, rising by £25 annually to £825, less a deduction of £125 per annum in respect of full residential emoluments.

Applications might be considered from married men prepared to provide their own accommodation in the immediate vicinity of the hospital; in the case of a non-resident appointment the deduction for emoluments would be correspondingly reduced.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and is subject to one month's notice on either side.

Further particulars of the appointment may be obtained on personal interview from the Secretary of the Hospital, to whom applications, stating age, experience and qualifications, with not more than three recent testimonials, should be sent not later than September 7th, 1937.

DUDLEY AUKLAND, Clerk of the Council.

DERBYSHIRE EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER (male).

The Derbyshire Education Committee require the services of an Assistant School Medical Officer—male—at a salary of £500, rising by annual increments of £25 to £700 per annum, together with a travelling allowance in accordance with the County scale.

Candidates must be registered Medical Practitioners of at least three years' standing. The duties will include work under the Maternity and Child Welfare Service. Experience in this work and in Mental Deficiency is desirable.

The appointment will be a designated post under the Local Government and Other Officers' Superannuation Act and the successful candidate will be required to pass a medical examination.

The Officer appointed will not be allowed to engage in private or consulting practice but will be required to devote his whole time to the duties of the office and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before Monday, September 6th, 1937, endorsed "Assistant School Medical Officer."

The appointment will be terminable by three months' notice on either side.

W. M. ASH, School Medical Officer.

New County Offices, St. Mary's Gate, Derby.

CAITHNESS COUNTY COUNCIL.

The County Council invite applications for the post of SURGICAL SPECIALIST for the COUNTY of CAITHNESS. Applicants must be of the status of Fellows of the Royal College of Surgeons. Salary £1,000 per annum, inclusive of travelling expenses, supplemented by fees from private surgical practice. The successful applicant will be expected to act as Consulting Surgeon to two Voluntary Hospitals by arrangement with the Managers.

The appointment will be subject to the approval of the Department of Health for Scotland in terms of a Scheme under the Highlands and Islands (Medical Service) Grant Act, 1913. Further particulars of the post may be obtained from the Subscriber, to whom applications, with six copies of testimonials, shoud be lodged by September 10th, 1937.

County Offices, Wick. JAMES ROBERTSON, County Clerk.

August 14th, 1937.

CITY OF BRADFORD.

MUNICIPAL GENERAL HOSPITAL, ST. LUKE'S.

HOUSE PHYSICIANS and HOUSE SURGEONS required.

Salary in each case £150 per annum, plus board and lodgings. These appointments are for six months, renewable for a further period of six months.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to the undersigned not later than August 30th, 1937.

N. L. FLEMING, Town Clerk.

Town Hall, Bradford.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

ROYAL NAVAL DENTAL SERVICE.

The Establishment of DENTAL OFFICERS in the Royal Navy has been increased, and applications are invited for EIGHT APPOINTMENTS to be filled in October next. Further appointments will be offered later.

Candidates must be British subjects of pure European descent and sons of persons who are British subjects. They must be under the age of 28 years on the date of entry, possess the degree or diploma of a British University or College of Surgeons, registered under the Dentists' Act in force in the United Kingdom, and physically fit for service in any climate. Unmarried candidates will be preferred.

Approved candidates will be required to present themselves at the Admiralty for physical examination by a Board of Naval Medical Officers and interview by a Selection Committee, and if selected for appointment will be given a Short Service Commission for six years. At the end of this period they will retire with a gratuity of £1,000 unless during the fifth year of service they have applied for, and have been accepted for, transfer to a Permanent Commission.

Candidates who have, since qualifying, held full time appointments as House Surgeons at Dental Hospitals and Schools will be eligible for an antedate of seniority up to a maximum of six months.

Application forms and a pamphlet showing the regulations for entry and outlining the conditions of service, rates of pay and allowances, etc., may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1.

Applications for entry in October must reach the Admiralty not later than September 1st.

CORPORATION OF DUNDEE

PUBLIC HEALTH DEPARTMENT.

ORTHOPTIC TRAINER.

An Orthoptic Training Centre is about to be established in the Public Health Department, and the services of a fully-qualified Orthoptic Trainer are required.

Salary will be at the rate of £225 per annum, rising by annual increments of £10, to £275 per annum.

Further information may be obtained on application to the Medical Officer of Health, Central Public Health Office, 9, West Bell Street, Dundee.

Applications, with copies of three recent testimonials, must reach the undersigned on or before September 4th, 1937.

City Chambers, Dundee. DAVID LATTO.
August 14th, 1937. Town Clerk.

HOLLAND (LINCOLNSHIRE) COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER OF HEALTH (male or female)

Applications are invited from duly qualified and registered Medical Practitioners (under 40 years of age) for the above appointment.

The salary will be £600 per annum, rising by annual increments of £25 to £700 per annum.

The duties of the post include school medical inspections, the carrying out of work under the Maternity and Child Welfare and Tuberculosis Schemes, and such other duties as may be required by the Council.

The person appointed will devote the whole of his or her time to the duties of the office, act under the direction and supervision of the County Medical Officer, and reside in such part of the district as may be required.

Post-graduate experience in the diagnosis and treatment of tuberculosis and the possession of a Diploma in Public Health will be additional qualifications.

Applications on the prescribed form, obtainable from the undersigned, accompanied by copies of not more than three testimonials, must be addressed to the County Medical Officer of Health, County Hall, Boston, Lincs, and received by him not later than September 7th, 1937.

W. G. BOOTH,
County Medical Officer of Health.
County Hall, Boston.
August 7th, 1937

COUNTY BOROUGH OF EASTBOURNE.

ST MARY'S MUNICIPAL HOSPITAL.

RESIDENT HOUSE SURGEON.

Applications are invited from unmarried, registered Medical Practitioners for appointment as Resident House Surgeon at the above Hospital.

Salary £150 per annum, with board, residence, etc.

The appointment is for twelve months, determinable at any time by one month's notice.

Application forms, together with conditions of appointment and duties, can be obtained from the undersigned. The application form, when completed, should be returned to me not later than September 4th, 1937.

W. G. WILLOUGHBY,
Medical Officer of Health.
Avenue House, The Avenue,
Eastbourne.

CITY OF NOTTINGHAM. HEALTH DEPARTMENT.

ASSISTANT TUBERCULOSIS OFFICER.

Applications are invited for the appointment of Assistant Tuberculosis Officer (whole-time).

Applicants should be registered medical practitioners, preferably holding a Diploma in Public Health, and must have had special experience in the diagnosis and treatment of Pulmonary Tuberculosis, including the use of X-rays for diagnosis.

Applicants must be prepared to assist by lecturing and otherwise, in the development of an anti-tuberculosis campaign.

The salary will be on the scale of £500 per annum, rising by annual increments of £25 to £700, but in assessing the commencing salary, allowance will be made for previous service in an established position with another Local Authority.

The salary will be subject to deductions in accordance with the terms of the Local Government and Other Officers' Superannuation Act, 1922.

The successful applicant will be obliged to live within the boundaries of the City of Nottingham, and, to terminate the appointment, one month's notice from either side will be required.

Forms of application may be obtained from the undersigned, by whom applications must be received not later than September 6, 1937.

The Guildhall J. E. RICHARDS.
Nottingham Town Clerk.
August 14, 1937.

SALOP COUNTY COUNCIL.

MEDICAL INSPECTION OF SCHOOL CHILDREN AND MATERNITY AND CHILD WELFARE SCHEMES.

Applications are invited from registered Medical Practitioners for the post of ASSISTANT MEDICAL OFFICER to work under these Schemes. Salary £560 per annum, rising by annual increments of £25 to a maximum of £700, with travelling and out-of-pocke. expenses on a fixed scale. The salary will be subject to a deduction of 5 per cent. for superannuation under the Local Government and Other Officers' Superannuation Act, 1922, and the candidate selected will be required to pass a medical examination.

Preference will be given to candidates with a Public Health Qualification, and experience in Refraction work is desirable. Forms of application can be obtained from the County Medical Officer of Health, County Health Offices, Shrewsbury, to whom they should be returned not later than September 4th, 1937.

THE KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered medical practitioners for the following posts:—

(*a*) AREA ASSISTANT TUBERCULOSIS PHYSICIAN (male). Salary £500 per annum, rising by annual increments of £25 to £700 per annum, together with travelling and subsistence allowances when away from base.

Preferably candidates should have had at least six months' special training in tuberculosis, with eighteen months experience in general clinical work, of which six months should have been spent in a hospital not confined to the treatment of tuberculosis. Knowledge of Welsh desirable.

The person appointed will be required to pass a medical examination and to contribute 5 per cent of his salary to the Superannuation Fund of the Association. Applicants not already in the service of the Association must be under 45 years of age.

(*b*) RESIDENT MEDICAL OFFICER (male or female, single) at the Adelina Patti Hospital (126 beds for male and female pulmonary and children surgical cases), Craig-y-nos, Swansea Valley. The appointment is tenable for one year.

Salary £350 per annum plus maintenance.

Preference will be given to applicants who have held the post of House Physician or House Surgeon at a general hospital and have had institutional experience in the treatment of pulmonary tuberculosis.

(*c*) ASSISTANT RESIDENT MEDICAL OFFICER (male, single—one year appointment) at the following institutions:—

(*i*) North Wales Sanatorium (247 beds for female pulmonary and male, female and children non-pulmonary cases), Denbigh, North Wales.

(*ii*) Glan Ely Hospital (196 beds for pulmonary and surgical tuberculosis in men, women and children), Fairwater, near Cardiff.

Salary £200 per annum, plus maintenance.

(*d*) HALF-TIME ASSISTANT TUBERCULOSIS OFFICERS (three in number) to be attached to the Cardiff, Newport, and Pontypridd areas respectively, and commencing duty on October 1st, next. The appointments are limited to one year at a remuneration for the year of £250. During their tenure successful candidates will be expected to take during the other half of their time the Course for the Diploma in Tuberculosis Diseases (Wales) at the Tuberculosis Department, Welsh National School of Medicine, and afterwards sit the examination. Particulars as to fees for this course can be obtained from the Secretary, Welsh National School of Medicine, Cardiff.

Applicants must have held a house appointment in medicine or surgery for at least six months in a general hospital, and must also have held either a post as resident for a period of 12 months in an institution for the treatment of tuberculosis (medical or surgical) or a period of whole-time work accepted by the Senate as equivalent thereto.

Applications, stating age, qualifications, experience, etc., together with copies of three recent testimonials, should reach the undersigned not later than Wednesday, August 25th, 1937.

D. A. POWELL,
Principal Medical Officer

Memorial Offices, Westgate Street, Cardiff.
August 9th 1937

CITY OF SHEFFIELD.
NETHER EDGE HOSPITAL.

Applications are invited from duly qualified medical women for the appointment of RESIDENT ASSISTANT MEDICAL OFFICER, which is vacant on October 1st next at the above Hospital.

The Medical Officer appointed will be required to assist in the medical and maternity work of the Hospital, and to assist daily at the Maternity and Child Welfare Centre, where Ante-Natal, Post-Natal and Child Welfare Clinics are conducted.

Candidates should have previous hospital experience, and post-graduate experience in Midwifery and Ante-Natal work is essential.

The salary offered is £350 per annum, rising by £25 to £450, with the usual residential allowances.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and deductions will be made under this Act.

Applications, stating age, qualifications and experience, accompanied by three recent testimonials, should be sent to the Medical Superintendent, City General Hospital, Sheffield, 5, on or before August 23rd, 1937.

CITY OF SHEFFIELD.
KING EDWARD VII HOSPITAL. RIVELIN VALLEY ROAD.

RESIDENT ASSISTANT MEDICAL OFFICER (woman) required on October 1st for the above Hospital, which is for the treatment of Surgical Tuberculosis and other orthopaedic conditions (140 beds). The officer appointed will be required to attend the Out-Patient department for Surgical Tuberculosis and the Orthopaedic Clinic of the Maternity and Child Welfare Centre.

Salary at the rate of £200 per annum, with board and laundry.

Appointment for twelve months.

Applications, with testimonials, should be sent to the Medical Superintendent

LIVERPOOL COUNTY BOROUGH LOCAL EDUCATION AUTHORITY.
ASSISTANT SCHOOL MEDICAL OFFICERS.

Applications are invited for Two Assistant School Medical Officers in the Department of the Medical Officer to the Local Education Authority, at a salary in each case of £500 per annum, rising by annual increments of £25 to £700 per annum.

(Where a successful candidate holds a similar appointment under another Local Education Authority, and receives a salary in excess of the advertised minimum, a commencing salary of not less than the salary which the candidate is receiving, under his (or her) existing appointment (not exceeding the maximum under the Liverpool Scale) may be paid.)

Candidates must be registered medical practitioners, and must have had at least three years' experience. It is desirable that they should have had some special experience in school hygiene and in diseases of children.

The officers appointed will be required to reside within the City, and devote whole-time service to the Local Education Authority under the direction of the Medical Officer to the Local Education Authority, and will not be allowed to undertake any private practice.

The appointments will be subject to the Local Government and Other Officers' Superannuation Act, 1922, and the Standing Orders of the City Council.

Form of application, which may be obtained by forwarding a stamped addressed foolscap envelope, should be returned, together with copies of three recent testimonials, to the undersigned not later than August 28th, 1937, and endorsed "Assistant School Medical Officer."

The canvassing of members of the Education Committee or the City Council is strictly prohibited, and will be considered a disqualification.

Municipal Buildings, Liverpool, 2.
August 13th, 1937.

W. H. BAINES,
Town Clerk and Clerk to the Local Education Authority.

COUNTY BOROUGH OF GATESHEAD.
ASSISTANT MEDICAL OFFICER OF HEALTH —FEMALE

Applications are invited from duly qualified medical women in possession of the Diploma of Public Health or similar qualification for the post of Assistant Medical Officer of Health in the Public Health Department. The person appointed shall work under the general supervision and control of the Medical Officer of Health. The salary payable is at the rate of £500, rising to £700 by annual increments of £25, and the appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. Applicants should have had special experience in practical midwifery and diseases of children. The appointment will be terminable by one month's notice from either side.

A list of the duties of the office may be obtained from the Medical Officer of Health, Greenesfield House, Mulgrave Terrace, Gateshead, to whom applications, stating age and experience and accompanied by not more than three recent testimonials, should be sent not later than August 30th, 1937, in envelopes endorsed "Assistant Medical Officer."

J. W. PORTER,

SURREY COUNTY COUNCIL.
WARREN ROAD HOSPITAL, GUILDFORD. (250 Beds.)

APPOINTMENT OF RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from Registered Medical Practitioners for the appointment of Resident Assistant Medical Officer at the Warren Road Hospital, Guildford. The Hospital is administered by the Public Assistance Committee of the Council: it is a preliminary training school for nurses, and the work undertaken includes a considerable proportion of acute work.

Applicants should have had experience as a House Surgeon or Physician. The appointment is for a period of six months, renewable for a further period of six months, and the salary is at the rate of £375 per annum, less a deduction at the rate of £125 per annum in respect of board, lodging and laundry.

The successful applicant will be required to commence duty early in October, 1937.

Applications, stating age, qualifications and experience, and enclosing copies of not more than three recent testimonials, should be endorsed "Resident Assistant Medical Officer," and sent to the County Medical Officer, County Hall, Kingston-upon-Thames, so as to reach him not later than August 25th, 1937.

DUDLEY AUKLAND,
Clerk of the Council.

County Hall,
Kingston-upon-Thames.
August 5th, 1937.

CITY OF PERTH
MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Medical Officer of Health of the City of Perth. Candidates must possess the necessary Public Health qualifications. (D.P.H. or equivalent.)

The appointment will carry a salary at the rate of £800 per annum, rising to £850 in two years, and will be subject to the Perth Corporation Superannuation Scheme.

The successful applicant must devote his whole time to his duties, which will include the supervision of, and responsibility for, all medical services controlled by the Town Council.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, to be lodged with the Subscriber not later than August 31st, 1937.

ROBT. ADAM,
Town Clerk.

City Chambers, Perth,
August 5th, 1937.

COUNTY COUNCIL OF THE WEST RIDING OF YORKSHIRE.
SCALEBOR PARK MENTAL HOSPITAL.

The Visiting Committee of the Scalebor Park Mental Hospital invite applications for the appointment of ASSISTANT MEDICAL OFFICER at the Scalebor Park Mental Hospital for private patients.

Salary £650 per annum, rising by annual increments of £25 to £750, with board and residence at the hospital.

Further particulars and form of application may be had from the undersigned, by whom all applications, together with copies of not more than three recent testimonials, must be received not later than August 28th, 1937.

J. CHARLES McGRATH,
Clerk to the Visiting Committee.

County Hall,
Wakefield.

COUNTY OF LONDON.

APPOINTMENT OF CORONER to fill vacancy caused by the death of Dr. Edwin Smith.

THE LONDON COUNTY COUNCIL invites applications, to be received not later than Friday, September 17th, 1937, for the appointment of a CORONER FOR THE COUNTY OF LONDON, who will probably be allocated to the western district of the County. This appointment is additional to that already advertised in relation to the eastern district, applications for which are due by August 31st, 1937.

The salary attached to the office is £1,700 a year, inclusive. The Coroner will be required to provide at his own expense any necessary office accommodation and clerical assistance and to defray all other expenses of the office (including the services of an approved deputy, and, if appointed, an assistant deputy), except actual disbursements under the approved schedule of fees, etc. Candidates, who must be not less than 35 or more than 50 years of age on August 31st, 1937, must be barristers or solicitors and possess one of the qualifications required by Section 1 of the Coroners (Amendment) Act, 1926. Due weight will be given to experience as deputy coroner and to the possession of a knowledge of forensic medicine. A pension is payable on retirement under an approved scale. The candidate appointed must give an undertaking to give his whole time to the duties of his office.

Application must be made on the official form, a copy of which, containing full particulars, may be obtained by sending a stamped addressed foolscap envelope to the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. Canvassing disqualifies.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing to undermentioned positions. Experience in a Resident appointment in a General Hospital for at least six months desirable. Married quarters not available.

ASSISTANT MEDICAL OFFICERS (Grade I). —Salary £350—£25—£425, with board, lodging and washing.

(a) COLINDALE HOSPITAL, The Hyde, Hendon, N.W.9.—(Two positions.)

ASSISTANT MEDICAL OFFICERS (Grade II). —Salary £250 a year, together with board, lodging and washing. Appointment for one year only in first instance (renewable for a second year under certain conditions).

(b) COLINDALE HOSPITAL, The Hyde, Hendon, N.W.9.

(c) KING GEORGE V SANATORIUM, Godalming, Surrey.

Experience in the treatment of pulmonary tuberculosis essential for all the above positions.

There is no accommodation for women officers.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division, 2a, County Hall, S.E.1, returnable by August 30th.

Canvassing disqualifies.

THE ROYAL EASTERN COUNTIES INSTITUTION
for the Mentally Defective, Colchester.

ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the above post, from unmarried male Medical Practitioners not over 36 years of age. Total beds over 1,700.

The medical man appointed will be stationed at the new Extension, Turner Village, and will be required gradually to assume responsibility for administrative work connected with that extension, which has at present over 400 beds. For that reason the commencing salary has been fixed at £400 per annum, together with furnished apartments, board laundry, and attendance. No deductions. Previous specialisation in Mental Deficiency is not essential.

A Research Department, with a Medical Director and other Staff, working under the Medical Research Council and the Rockefeller Foundation, is attached to the Institution. New Laboratories costing nearly £5,000 will be ready for occupation in October and there is every facility for research work.

Apply before September 8th, giving age, nationality, full details of qualifications, and copies of testimonials, to the Medical Superintendent, Royal Institution, Colchester.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

Applications are invited for the post of HOUSE SURGEON, vacant on September 13th, 1937. The appointment will be for six months but is terminable at an earlier date by one month's written notice on either side. Salary at the rate of £130 per annum, with board, residence and laundry. Candidates (male), who must be unmarried and duly registered, are requested to forward their applications, stating age, qualifications, etc., together with copies of not more than four testimonials, to the undersigned on or before Wednesday, September 1st, 1937.

J. A. BEARDSALL,
Secretary-Superintendent.

BOROUGH OF CHELMSFORD.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners possessing the Diploma of Public Health for the appointment of Medical Officer of Health for the Borough, subject to the provisions of the Local Government Act, 1933, the Sanitary Officers (Outside London) Regulations, 1935, and the Local Government and Other Officers' Superannuation Act, 1922.

The officer appointed will be required to perform all the duties generally appertaining to the position of Medical Officer of Health, to act as School Medical Officer, to undertake work in connexion with Maternity and Child Welfare, and to carry out all such duties as the Council may from time to time direct. He will be required to reside in the Borough unless otherwise authorised by the Council and must devote his whole time to the duties of the office and must not engage in private practice.

He may, if appointed to that position, also be required as part of his duties to undertake the medical supervision of the Infectious Diseases Hospital, which is under the control of the Chelmsford Joint Hospital Board, in which event a proportion of his total salary will be paid by the Joint Hospital Board.

The salary offered to cover all the duties specified above (including the Infectious Diseases Hospital) will be £800 per annum.

Full particulars and terms of appointment may be obtained upon application to the undersigned, and applications, on the form provided, should reach me not later than Monday, September 6th, 1937.

Canvassing is forbidden.

Municipal Offices, Rainsford House, Chelmsford. August 18th, 1937.

C. E. BARFORD,
Town Clerk.

COUNTY BOROUGH OF WEST BROMWICH.
HALLAM HOSPITAL. (472 Beds.)

HOUSE PHYSICIAN AND HOUSE SURGEON.

Applications are invited from duly qualified male registered practitioners for the above-mentioned posts. The post of House Surgeon will also include duties in the Maternity Wards (30 beds).

The appointments are for six months, with eligibility for a further six months. Either party may give six weeks' notice terminating the appointment. There is a visiting staff of eight physicians and surgeons, one resident surgical officer and three resident medical officers.

Salary £200 per annum, and also board-residence. All fees received by the persons appointed will be payable into the funds of the Council.

Applications, stating age, experience and qualifications, together with copies of three recent testimonials, must be forwarded to the Medical Officer of Health, 2, Lodge Road, West Bromwich, so as to arrive not later than by first post on Saturday, September 4th, 1937.

Canvassing, either directly or indirectly, is strictly prohibited, and will be deemed a disqualification.

Town Hall, West Bromwich. August 20th, 1937.

ALFRED WICKHAM,
Town Clerk.

LANCASHIRE COUNTY COUNCIL

JUNIOR ASSISTANT MEDICAL OFFICER, WRIGHTINGTON HOSPITAL, APPLEY BRIDGE.

Applications are invited for the post of Junior Assistant Medical Officer (male, unmarried) for the Wrightington Hospital, which contains 206 beds for non-pulmonary tuberculosis (adults and children) and 20 beds for "combined" pulmonary and non-pulmonary cases. Salary £200 per annum, together with board, residence and laundry.

The appointment will commence on October 1st, or thereabouts, and will be for 12 months.

The medical staff consists of medical superintendent, two assistants, two consultant orthopaedic surgeons and other visiting surgeons. There are excellent facilities for reading for M.D.

Forms of application and conditions of appointment obtainable from Central Tuberculosis Officer, County Offices, Preston. Letters to be marked "Wrightington M.O."

Closing date September 3rd.

GEORGE ETHERTON,
Clerk of the County Council.

SHOP WINDOWS

Who is not tempted to glance at the goods displayed in the shop windows which brighten the streets of every town? The subtle attraction of articles thus brought to notice cannot be explained by any immediate need to purchase. Indeed, the majority of the contents of shop windows have no immediate appeal. They are seen and a mental note is made which may well prove useful later on.

So it is with the advertisements in the *British Medical Journal*. Sometimes, it is true, the reader searches these pages to find a particular preparation or appliance for use in the treatment of a specific case. More often the advertised products are noticed and remembered pending their being required at some future time.

In this way an up-to-date knowledge of proprietary aids to medical practice can be maintained without expense and with very little expenditure of time.

Two helpful suggestions: Pages may be cut out and filed for future reference, and it is always worth while to mention the B M J. when writing to advertisers

APPOINTMENTS.—Contd.

WEST LONDON HOSPITAL, HAMMERSMITH ROAD, W.6. (239 Beds.)

Required first week in September, one RESIDENT ANAESTHETIST (male). The appointment is tenable until March 31st, 1938, subject to one month's notice on either side. Salary at the rate of £100 a year, with board, lodgings and laundry allowance.

Candidates must be registered under the Medical Act. Applications (which must be made on printed forms, obtained from me) must reach me not later than first post on Friday, August 27th. Selected candidates will be required to call upon such members of the Medical Staff as directed; to be in attendance at the Medical Council Meeting on Friday, September 3rd, at 4.30 p.m., and the House Committee Meeting at 5 p.m. the same day, when the appointment will be made.

H. A. MADGE,
Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY ROAD, LONDON, E.2.

RESIDENT MEDICAL OFFICER required on *October 1st, 1937.*

The appointment is made for six months, and may be extended for further periods of six months, but cannot be held for more than two years.

The Resident Medical Staff consists of the Resident Medical Officer as above, three Casualty Officers, two House Physicians, and one House Surgeon.

Salary £200 per annum, with board, residence and laundry. Candidates must have held a responsible resident appointment at a recognised hospital.

Forms of application may be obtained from the undersigned, and must be completed and returned on or before September 6th.

CHARLES H. BESSELL,
August 1st, 1937. Secretary.

KING EDWARD MEMORIAL HOSPITAL, EALING. (131 Beds.)

Applications are invited for the post of HOUSE SURGEON (male) to act in the Eye, Gynaecological and Ear, Nose and Throat Departments. Six months' appointment with possibility of re-election for a further period. Salary £150 per annum, with usual residential emoluments.

Applications, stating age, experience and qualifications, and accompanied by copies of two recent testimonials, to be sent to the undersigned immediately

R. A. MICKELWRIGHT,
House Governor.

ISLINGTON DISPENSARY. Founded 1821. 303, Upper Street, N.1.

Applications are invited for the post of JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER (lady, unmarried). Salary £200 per annum, with furnished apartments. Applicants must be registered Medical Practitioners.

Applications not later than September 1st, on printed form to be obtained (by postcard) from the Secretary at the Dispensary.

THE MANOR HOUSE HOSPITAL, Golders Green, London, N.W.11.

Applications are invited for the post of JUNIOR MEDICAL OFFICER. Salary at the rate of £200 per annum, with board-residence. Candidates, male and unmarried, must be fully qualified and registered. Applications, stating full particulars and accompanied by copies of not more than three recent testimonials, should be addressed to reach the undersigned as soon as possible.

JAMES W. LINKHORN, F.C.C.S.,
Secretary.

THE PRINCE OF WALES'S GENERAL HOSPITAL, London, N.15.

The following Resident posts will be vacant on September 15th next:—

(*a*) ONE JUNIOR HOUSE PHYSICIAN.
(*b*) TWO JUNIOR HOUSE SURGEONS.

Salary at the rate of £90 per annum, board, residence and laundry.

Appointments held for six months, but holders are eligible for a further term as Senior.

Candidates (male and unmarried) must be fully qualified and registered, and applications (on the prescribed form), together with copies of three recent testimonials, should be sent to the undersigned on or before Wednesday, September 1st, 1937.

J. C. BURDETT,
Director and House Governor.
August 5th 1937.

THE PRINCESS ELIZABETH OF YORK HOSPITAL FOR CHILDREN, Shadwell, London, E.1. (Formerly East London Hospital for Children.) (135 Beds.)

A HOUSE PHYSICIAN is required on October 1st, 1937, by the above Hospital. Candidates are invited to send in their applications, addressed to the Secretary, by noon on Wednesday, September 1st, at the latest, accompanied by copies of not more than three recent testimonials and particulars of previous appointments, if any. The appointment is for six months. Salary at the rate of £125 per annum, with board, residence and laundry. Candidates must be properly registered in this country. Forms of application and copies of the rules can be obtained from the Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, London, E.2.

HOUSE PHYSICIAN required October 1st, 1937. CASUALTY OFFICER required October 1st, 1937. Some Ear, Nose and Throat work additional.

Six months' appointments. Salary at the rate of £100 per year, with board, lodging, and laundry in each case.

Applications must be made on forms to be obtained from the undersigned, and must be sent in with copies of not more than four testimonials, on or before September 6th.

CHARLES H. BESSELL,
August 10th, 1937. Secretary.

THE ROYAL CANCER HOSPITAL (FREE) (Incorporated under Royal Charter). Fulham Road, London, S.W.3.

Applications are invited for the two posts of ASSISTANT RADIOLOGIST at this Hospital.

Applicants must be registered Medical Practitioners, who hold a Diploma in Radiology.

The appointments will be for one year, commencing on October 1st, 1937, at a salary at the rate of £150 per annum each.

Applications, to be made on a form which will be supplied by the Secretary, together with three (copies only) recent testimonials, should be sent to the Secretary on or before Wednesday, September 8th, 1937.

CLEMENT COBBOLD,
Secretary.

THE ROYAL CANCER HOSPITAL (FREE). (Incorporated under Royal Charter.) Fulham Road, London, S.W.3.

Applications are invited for the post of HOUSE SURGEON to commence duties on October 1st, 1937.

Salary at the rate of £100 per annum.

The appointment is for six months and subject to rules, a copy of which may be obtained from the Secretary.

Applications, to be made on a form which will be supplied by the Secretary, together with three (copies only) testimonials, to be sent to the undersigned not later than the first post on Wednesday, September 8th, 1937.

CLEMENT COBBOLD,
Secretary.

THE SALVATION ARMY. The Mothers' Hospital, Lower Clapton Road, Clapton, E.5.

Applications are invited from Medical Women for the post of SENIOR RESIDENT MEDICAL OFFICER, vacant October 1st, 1937. Salary £150 per annum, with board, residence and laundry. The appointment is for twelve months.

Applications, with testimonials, must be sent to the Secretary on or before Monday, September 6th, 1937.

EDGAR DIBDEN,
Secretary.

PRINCESS LOUISE KENSINGTON HOSPITAL FOR CHILDREN, St. Quintin Avenue, North Kensington, W.10.

CLINICAL ASSISTANT required for Out-patient Department session (Medical) on Thursday mornings.

Applications, giving details of qualifications, with copies of two recent testimonials, should be sent to the undersigned as soon as possible.

H. J. ELEY,
Secretary.

JEWISH MATERNITY HOSPITAL, Underwood Street, London, E.1.

RESIDENT MEDICAL OFFICER required. Board, residence and laundry provided with salary at the rate of £50 per annum. The appointment is for four months, with option of extension to six months. Applicants may be male or female. Applications, accompanied by copies of three testimonials, should be forwarded to the Secretary, immediately.

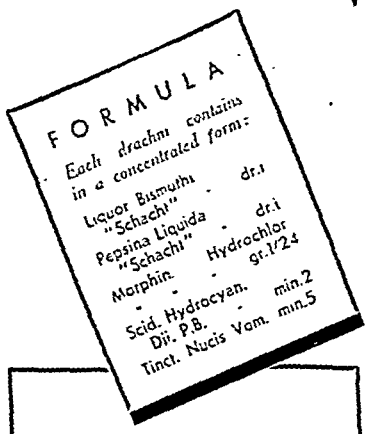
The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.
No charge is made to Principals for the introduction of Locum Tenens or Assistants.



1. NORTH-WEST COAST.—Well-established PRACTICE, with seaside town and country work, producing £1,299, including panel and appointments worth about £400 p.a. Suitable house with 3 bedrooms, etc., garden, garage. Rent £50 p.a. Sport of all kinds. Premium only £1,250 for quick sale.
2. NORTH-EAST COAST.—Well-established non-panel PRACTICE, averaging about £800 p.a., but capable of extension as considerable building is in progress. Very good house, with 6 bedrooms, etc. Price £1,500. Premium 1½ years' purchase.
3. SOUTH COAST.—PARTNERSHIP.—A ONE-HALF SHARE in good middle and upper-class practice producing about £2,550 p.a. Panel of 1,300. Fees 3/6 to 21/-. Suitable house can be rented at £65 p.a. Easily worked, and scope for increase. Premium 2 years' purchase.
4. LONDON, EAST.—Good working class PRACTICE producing over £1,100 p.a., with panel of 1,800. Suitable house can be rented at £80 p.a. Premium 2 years' purchase.
5. LONDON, EAST.—PRACTICE established 30 years, and producing £1,400 p.a., including panel of 1,800, and appointments worth £236. Small house, with 1 sitting, 2 bedrooms, etc. Rent £60. Premium 2 years' purchase.
6. NORFOLK AND SUFFOLK BORDERS.—A TWO-FIFTHS SHARE, with increase to one-half, is offered in an old-established practice with considerable scope for increase. Receipts approximately £3,300, with panel of about 1,400. Low expenses. Good house available.
7. SURREY.—Pleasant district in outskirts of London.—A 5/9TH SHARE is offered in an old-established practice producing for the past 12 months about £4,500. Panel of approximately 1,800 patients. Good house available on rental. Ingoing man should be over 30, married and preferably a Protestant.
8. BORDERS OF HAMPSHIRE AND BERKSHIRE.—Old-established country PRACTICE. Receipts for past 12 months about £1,200 including £372 from panel of about 660 patients. Suitable house available on rental at £70 p.a. approximately inclusive. Premium £1,550.
9. DEVON COUNTRY.—Old-established PRACTICE producing about £800 p.a. including about £310 from panel of 428 patients. Freehold house for disposal containing 2 reception rooms, lounge hall, 6 bedrooms, waiting room, consulting room, etc., 1½ acres of garden, garage for 2 cars and stabling. Freehold £2,600. Premium £1,200.
10. CENTRAL LONDON.—Owing to illness, old-established PRACTICE producing about £2,300 p.a. Panel of over 3,100 patients. Suitable accommodation available on rental. There is an appointment producing £160 p.a. which is not included in the above receipts but which is believed to be transferable.
11. LANCS.—Suburb of large town. PRACTICE producing about £800 p.a. with panel of 467 patients. Suitable house on rental at £90 p.a. inclusive, Stated to be scope for increase. Premium £1,100.
12. DEATH VACANCY.—BAYSWATER, W. 2.—Good class PRACTICE producing about £840 p.a. but has been considerably more. Receipts have decreased owing to ill health. Fees 10/6—no panel. House available on rental or practice could be taken over separately. Premium 1 year's purchase.
13. LONDON, S.E. 11.—Old-established working class PRACTICE producing approximately £500 p.a.. Panel of about 500 patients. Can be worked as lock-up. Premium 1 year's purchase or any reasonable offer accepted.
14. YORKS.—LARGE TOWN.—Well-established better working-class PRACTICE. Receipts for last 12 months about £1,176 with Panel of 1,150 patients approximately. Fees, minimum 2/6 with visits from 3/6 to 7/6. Freehold house for disposal at £900 containing 3 bedrooms, 2 living rooms, surgery, waiting room, etc. Vendor wishes to specialise.
15. SURREY.—PLEASANT TOWN.—PRACTICE produced for past 12 months about £1,280 with a Panel of 800 patients. Fees 3/6 upwards, with visits from 5/- upwards. Midwifery 3 to 10 gns., about 15 cases per annum. Vendor has to give up owing to ill-health. Premium £2,000.
16. EASTERN COUNTY AND MARKET TOWN.—HALF-SHARE PARTNERSHIP in Practice established some 100 years owing to retiral of junior partner. Average cash receipts over £2,400 p.a., of which over £700 comes from Panel and P.A.C. Suitable house available on rental. Ingoing partner should not be more than 30, preferably have a degree and some hospital experience.
17. ASSISTANTSHIP—with a view to a PARTNERSHIP SHARE to produce about £1,100 p.a., in a well-established Practice. Ingoing man must be young, have had considerable hospital experience, and preferably held an Ophthalmic H.S. He should be married or engaged, and a Protestant. Will applicants please give full details of experience, etc.
18. DEVON, SOUTH COAST—A well-established good-class entirely private PRACTICE producing for the past 12 months about £1,000. Panel could be had if desired. Fees 2/6, 3/6, 5/- and 7/6, with a few visits up to 21/-. Non-dispensing. Suitable house containing consulting room, 2 reception rooms, 6 bedrooms, for sale. Freehold £1,400. Partnership introduction. Would be suitable for ex-I.M.S. or similar.
19. DEVELOPING NORTHERN SUBURB.—a 3/8TH SHARE is offered in a well-established and growing Practice. Receipts for 12 months to 1/4/37 amounted to about £5,200, including about £80 from appointments and a Panel of some 5,300 patients. There is a choice of houses available.
20. LANCS.—SUBURB OF LARGE TOWN.—PRACTICE established for 10 years—gross cash receipts for year ended 31/3/37 amounted to about £800, with an increasing Panel of some 470 patients. Fees 2/6 and 3/6, with visits 3/6 and 5/-. Suitable house with good accomodation and separate surgery available on lease at £60 p.a. Premium £1,100, plus good debts, drugs and surgery equipment at valuation. Vendor giving up owing to ill-health.
21. WEST COAST.—Well-established PRACTICE producing about £1,900 p.a., including Panel of 1,450 patients which gives £820 p.a. and one or two small appointments. Visits 3/6 to 12/6. Consultations 3/6, medicine extra. There is a Cottage Hospital, purchaser would get on the staff. There is stated to be scope for surgery. Suitable house on rental at £50 p.a., with rates of £26 p.a. Accommodation is ample, and consists of waiting and consulting room, dispensary with separate entrance, 2 reception, 7 bedrooms and billiard room, half-acre of garden and garage for 2 cars. Premium 1½ years' purchase.
22. WIMBLEDON.—Old-established PRACTICE for disposal. Gross income about £1,000 p.a., with Panel of 350 patients. There is also a possibility that the purchaser will obtain a hospital appointment worth about £120 p.a. House can be rented on lease or purchased.
23. LONDON, E.2.—Lock-up PRACTICE established 80 years for disposal. Income about £800-£900 p.a., with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available consisting of consulting room, dispensary, waiting room, the remainder being sub-let for £280 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £150 fittings, fixtures, drugs, etc.
24. CITY PRACTICE.—Lock-up, hours 10-1 and 5.30-6.30, producing about £1,000 p.a., including £200 from Panel and appointments. Suitable accommodation available.
25. BAYSWATER.—PRACTICE, established some 65 years for disposal. Gross receipts about £1,440 p.a., with 1,000 Panel patients. Suitable house on lease at £130 p.a. Premium 2 years' purchase.
26. ESSEX COAST TOWN.—A ONE-THIRD SHARE is offered to a physician in an old-established Practice producing about £7,200 p.a. Panel produces about £900 p.a. Consultations 3/6 to 7/6. Visits 5/- to 21/-. There will probably be a choice of houses. Ingoing partner should be aged 35 or over and must have a good hospital experience. He should hold the M.D. or M.R.C.P.
27. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be 28-40, preferably hold a degree and must have their English Fellowship. Premium 2 years' purchase.
28. NORTH LONDON.—PRACTICE producing £758 p.a., including £322 from Panel and £135 from one appointment. Fees 2/6 to 3/6. Visits 3/6 to 5/-. Suitable accommodation available, 2 consulting rooms, waiting room and dispensary with separate entrance—2 reception rooms, 7 bedrooms. Nett outgoings approximately £107 p.a. Premium £1,250.
29. LONDON, S.W.—Old-established PRACTICE producing £1,500 p.a., with panel of 1,266 patients for disposal. Appointment and small club bring in about £85 p.a. House available contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. Premium £3,000.
30. NORTH-WEST COAST.—SEASIDE TOWN.—CONSULTING PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320. Minimum fee 2 gns. Suitable rooms available at inclusive rental of £64 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1½ years' purchase on actual receipts for first year.
31. HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc., Professional accommodation. Good garden and garage. Rent £55 p.a. Prem. £1,250.
32. LONDON, SOUTH-EAST.—Middle-class PRACTICE held by vendor nearly 30 years, averaging over £700 p.a. Panel of 576 and one appointment worth £25 p.a. Roomy house with good garden and garage. Leasehold for sale.
33. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¾ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house might be rented for a short period.
34. LONDON.—WESTERN SUBURB.—Old-established private PRACTICE producing about £1,100 p.a. for disposal. There is stated to be good scope for a young man who will undertake panel and midwifery. Fees 3/6 to 10/6. Small compact house on rental. Premium £1,800.
35. SOUTH-COAST SEAPORT.—Long-established PRACTICE for disposal owing to Vendors retirement. He has held it for the past 39 years. Income last year approximately £573 with a Panel of about 460 patients. Vendor previously held a public appointment producing £450 p.a., which he relinquished owing to age limit. It is considered that anyone devoting whole time to the Practice would increase the receipts. Suitable accommodation available on rental.
36. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last twelve months over £1,300 p.a. Fees 3/6 to 21/-. Nice house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, garage. Price for freehold £1,300. Sport of all kinds and schools within reach.
37. EAST ANGLIA—WITHIN REACH OF TWO GOOD TOWNS.—Old-established, unopposed country PRACTICE averaging over £1,000 p.a., including Panel producing over £450 a year. Low expenses. Detached house in own grounds, containing 2 sitting rooms, 5 bedrooms, etc. Rent £70 a year. Premium £1,750.
38. LONDON—NORTH-WEST.—Recently established and steadily developing PRACTICE producing for last 12 months approximately £1,000, and increasing at the rate of about £200 p.a,. Suitable house can be rented or flat obtainable. Premium 2 years' purchase.
39. NORTH-EAST COAST.—Old-established PRACTICE producing about £900 p.a., but stated to be capable of considerable increase. Choice of houses Partnership introduction given, as vendor retiring.
40. MIDLANDS.—FAVOURITE RESIDENTIAL TOWN.—Chiefly better class non-dispensing PRACTICE, producing for last 12 months over £1,600. Panel of 560 and one appointment worth £150 p.a. Fees 3/6 to 21/-. Very nice house with ample accommodation, garden and garage. Freehold for sale. Premium 2 years' purchase.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Measured by any and every standard Numol has proved its value for the convalescent patient

A TYPICAL OPINION

Extract from a letter received in May, 1937:—

"*At the Annual Meeting of the County Tuberculosis Care Committee held last week a Medical Member of the Committee referred to your preparation Numol and spoke of the beneficial results he had experienced in patients taking it.*"

Doctors who have not already prescribed Numol are asked to send a post-card for a free sample.

CASE RECORDS

Case No. 2159/1472. 1935

Miss A., a hospital patient, aged 25 years, was sent to us in April, 1935. She had had both legs amputated below the knee eight years previously as a result of septicemia following an accident. Owing to general ill-health and lack of funds she had not been fitted with limbs but for seven years had managed to get about the house on her knees, causing deep-seated callouses to develop. See Figure 1. Apart from these callouses she had a good 7 in. left stump which was easily fitted with the normal below-knee limb. The right stump, on the other hand, was extremely short, only 1½ in. of tibia being left, and it appeared on first sight that the patient would have to be fitted with a kneeling appliance. However, on examination, it was found that as the leg had been amputated immediately below the tibio-fibula joint there was an exceptionally large bone surface which made it possible to use the end of the stump as a weight bearing point, and with the remanent of calf muscle being used to obtain a retaining grip, a normal below-knee type limb was fitted with only a slightly longer thigh corset to give additional lateral support. Although this is without doubt the shortest stump to which it is possible to fit a below-knee limb the patient has good control over both limbs and walks well with natural knee actions.

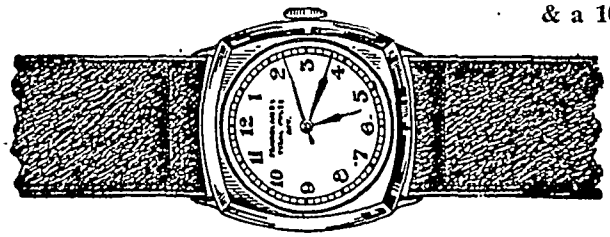
DIAGNOSIS AND NON-OPERATIVE TREATMENT OF THE DISEASES OF THE COLON AND RECTUM

By GOTTWALD SCHWARZ, M.D., Professor, University of Vienna; Head, X-ray Dept., Kaiserin Elizabeth Hospital, Vienna; Honorary Member, American Roentgen Ray Society, etc.; JACQUES GOLDBERGER, M.D., Consulting Physician, Carlsbad; and CHARLES CROCKER, M.D., New York.

"A professor of radiology and two consulting physicians working in collaboration, have much of interest to say about diseases of the colon and rectum. . . . Since the diseases discussed include many such as *diverticulitis, colitis, and proctitis*, which come under the survey of both surgeons and physicians, all clinicians will read it with profit."—LANCET.

"More than one-quarter of this well-illustrated book is devoted to the modern technique in X-ray examination of the colon and rectum. This portion of the book is of great value and importance. . . . All the various recent advances in technique and diagnosis are well described . . ."—PRACTITIONER.



". . . There is a great deal of practical value in the book . . ."—CLINICAL JOURNAL.

LODGE

THE BEST PLUG IN THE WORLD

Lodge plugs have unbreakable mica insulation. They are obtainable everywhere from 3/- each, in sealed metal boxes. Made completely in England by Lodge Plugs Ltd., Rugby.

THE "DOCTORS' SHIRT" *which has detachable sleeves!*

Here is a most useful shirt which for many years we have supplied to the medical profession. With detachable sleeves just above the elbow, it fastens with four small buttons which are adjusted with a minimum of trouble. The "Doctors' Shirt" possesses also these additional points of interest.

1. It keeps the cuffs smooth instead of being creased up by the process of rolling.
2. There is no fear of them coming down at an inopportune moment.
3. There is no muster of material about the biceps to interfere with the action of the arm.

The "Doctors' Shirt" is made in white poplin 10/6, Collars 1/3 extra. Extra half sleeves sold separately. Also other fabrics striped or plain. For prices, patterns, and self-measurement form send to Dept. B.M.J.

INFANTILE ECZEMA.

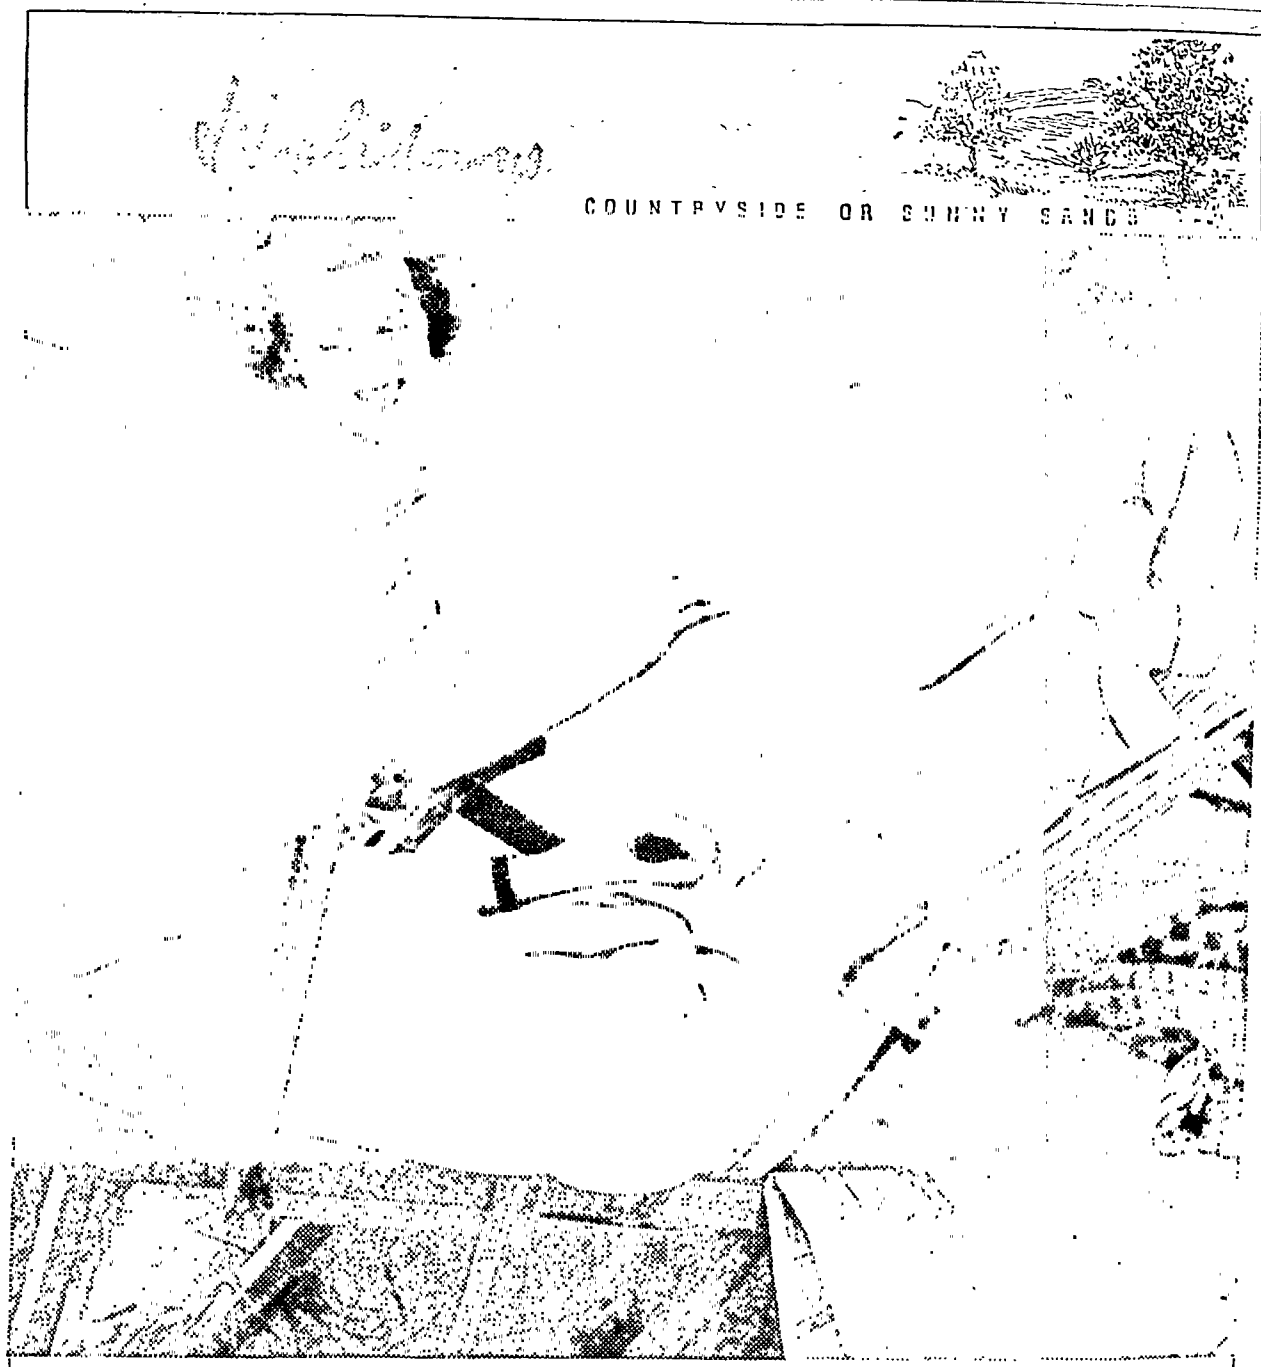
A quick cure—'would usually take months' writes doctor.

The doctor's letter:

". . . I happened to have in my consulting room a baby with eczema of the scalp, which would normally have taken me months to cure.

I tried it with Sphagnol Ointment with most satisfactory results, and am so pleased with the preparation that I should be grateful if you would forward me a pound package of it."

Yours truly,



———, M.B.

Reports of speedy cures with Sphagnol Ointment are not uncommon, but the great virtue of Sphagnol Ointment is this—that from the first touch it is soothing, cooling. Used against eczema, Sphagnol brings sure relief from itching, and at the same time its healing peat principle helps the growth of clear, healthy skin.

Perhaps you have had no personal experience of Sphagnol Then the makers will gladly send you free samples.

Sphagnol

Peat Products (Sphagnol) Ltd., Dept. B. 214, 21, Bush Lane, London, E.C.4.

—taste decides your choice

Lazing on a sunny beach, or rambling over the countryside—taste decides your holiday choice. And wherever you go Player's offer another choice to complete your pleasure —Player's "Medium" or "Mild" Navy Cut Cigarettes. Here again taste decides your choice. A vast multitude of smokers find "Medium" suit their tastes better than any other Cigarette. But the smokers who do prefer a very mild and smooth blend can also enjoy the unrivalled Player Tobacco by asking for Player's "Mild" Navy Cut Cigarettes —Cork Tipped or Plain as you wish—Remember "MEDIUM" OR "MILD"—IT'S THE TOBACCO THAT COUNTS.

The packets are similar in design, but with Blue wording on "Medium" and Red on the "Mild." Prices are the same. 10 for 6D 20 for 11½D

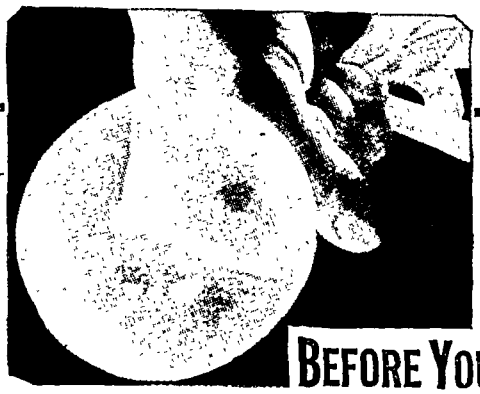
'Gas fires kill draughts but cure stuffiness' *says*



Mr. THERM (of Harley Street)

If you were to go into a room fitted with a modern gas fire, fill it with smoke, and then light the fire, you would see the smoke being gently but firmly sucked up the flue. In about twenty minutes the room would be clear!

A modern gas fire changes the air in a room three or four times every hour. It does so quietly and unobtrusively, creating no uncomfortable draughts. Stuffiness is equally impossible. That is because the modern gas fire emits an unusually large proportion of the shorter infra-red rays which warm the room (and its occupants) without drying or overheating the air.

GAS for healthy heat

MAKE THIS TEST

BEFORE YOU BUY SURGEONS' GLOVES

Inflate the end of a finger as fully as possible. Then look for tell-tale rubber "drip" mark at the tip of the finger! You'll find none in *Maderite* Surgeons' Gloves, for they are uniformly thin, yet tough throughout—moulded to the hand. No excess rubber anywhere, free from thickened spots or imperfections that dull your touch.

The "gloveless" feel of *Maderite* brown Milled Surgeons' Gloves is further emphasized by the accuracy of their anatomical design. They do not bind or resist. They co-operate with every move of your hands.

Try on a pair and note the secure and firm grip the roughened surface gives you on your instrument. See how well *Maderite* gloves fit and feel. They are made for their job and do it well. Made by the manufacturers of Seamless Standard Latex Surgeons' Gloves, the famous tissue thin, quality white gloves.

for RELIABILITY

'VARIBAN' ELASTIC PLASTER BANDAGE

"VARIBAN" BANDAGE constitutes a marked advance on the older methods of treating chronic ulceration of the leg. It is made from a specially woven selvedge material possessing highly elastic properties, and is impregnated with an antiseptic zinc oxide paste.

"VARIBAN" is self-adhesive and combines the principles of firm, equable pressure and support to the swollen leg, with the benefit of an occlusive dressing under which the ulcer is protected and is stimulated to healthy repair.

In promoting proper circulation, "VARIBAN" steadily reduces oedema. It provides protection to the granulations of the healing ulcer. In the majority of cases it is found that pain is either eliminated or greatly relieved from the first application. The necessity for ointments, lotions, etc., is obviated, while "VARIBAN" provides an ambulatory treatment which allows of full activity of the limbs with better results than those following rest in bed alone.

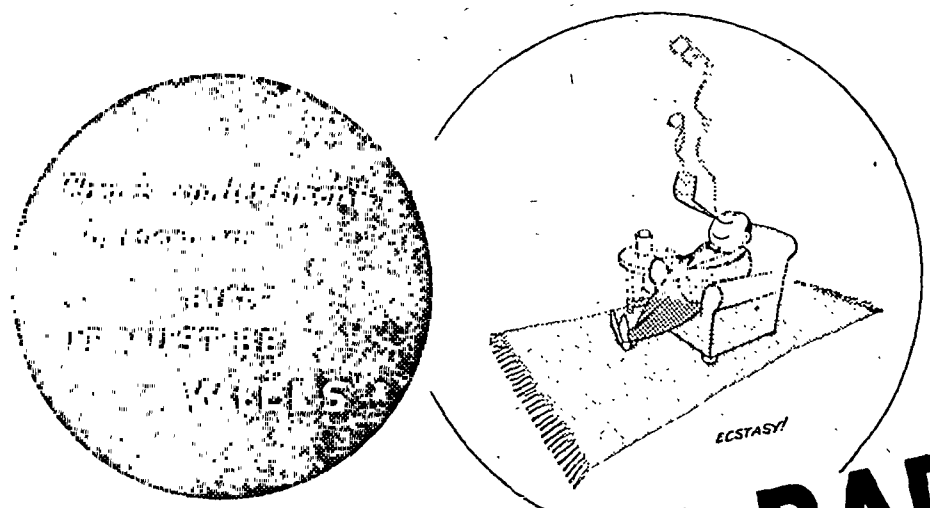
ANTERIOR-POSTERIOR PRESSURE
FOR THE MOST SATISFACTORY
SUPPORT



Effective support without constriction is made possible by the anterior-posterior pressure given by the Curtis Abdominal Support No. 1. This Support, one of over 100 abdominal appliances made by Curtis, gives steady, permanent support where it is most needed. Yet it is extremely light in weight and very comfortable in wear, giving perfect freedom to the hips. Medical Authorities throughout the world approve the Curtis Abdominal Support No. 1, and prescribe it for all cases where support upward and backwards of the lower abdomen is essential.

PRESCRIBE FAREX FOR A *tonic* BREAKFAST

Farex is liked in health and appreciated in sickness. Being pre-cooked and having a low fibre content, it is ready to serve, compact and very easily assimilated.

In health, Farex is sustaining. One tablespoonful doubles the calorie value of a cupful of milk without increase in bulk.

In sickness, Farex is the most suitable basis for the "light" diet prescribed in the treatment of many gastric, metabolic and nephritic disorders. Calcium, phosphorus, iron, trace minerals and vitamins A, B1, B2 and D are incorporated in Farex. The improvement in vigour and well-being obtained by a daily ration of this reinforced cereal food is specially marked when it is used as a supplementary tonic meal in debility.

Farex needs no cooking.

LIMITED, GREENFORD, MIDDLESEX. BYRon 3434.

FAREX
cereal food

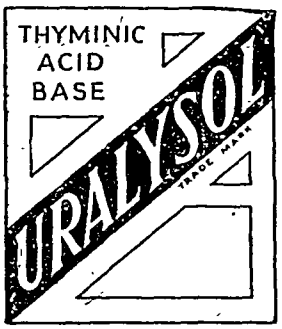
SUBSTANTIAL IN HEALTH ... SUSTAINING IN SICKNESS

Valentine's Meat-Juice

IN the Treatment of Weak Babies, in the Gastric and Enteric Troubles of Infants and in the Wasting and Febrile Diseases of Children, the Ease of Assimilation and Power of Valentine's Meat-Juice to Sustain and Strengthen has been Demonstrated in

Hospitals for Children.

The quickness and power with which Valentine's Meat-Juice acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.



Physicians are invited to send for Clinical Reports.

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY
RICHMOND, VIRGINIA, U.S.A.

JB 95

FORMULA

Thyminic Acid	0·10
Hexamethylenetetramine Anhydromethylenecitrate	0·50
Hexamethylene Tetramine	2·50
Piperazine Tartrate ..	0·25
Lithium Carbonate ..	1·00
Sodium Benzoate ..	1·00
Effervescent Base ..	ad 100

DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

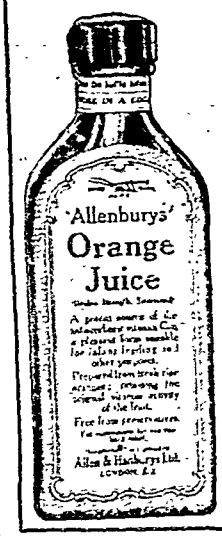
Uralysol, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

Samples and literature on request.

CONTINENTAL LABORATORIES LTD. 30 MARSHAM STREET, LONDON, S.W.1

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the proto-carbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and injury to the teeth is avoided.



The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.
The Iron 'Jelloid' Co. Ltd., King George's Avenue, Watford, Herts.

Double Strength Sweetened

Allenburys ORANGE JUICE

Supplies a potent source of the anti-scorbutic vitamin C in a form convenient for infant feeding and other purposes.

It is equivalent to *double strength* fresh orange juice and retains its full activity for a long period.

Employed with advantage in all cases in which fresh orange juice is used.

May be taken by children and adults in the form of a delightful drink by diluting with about ten times its volume of plain or aerated water or milk.

Contains no alcohol or chemical preservative.

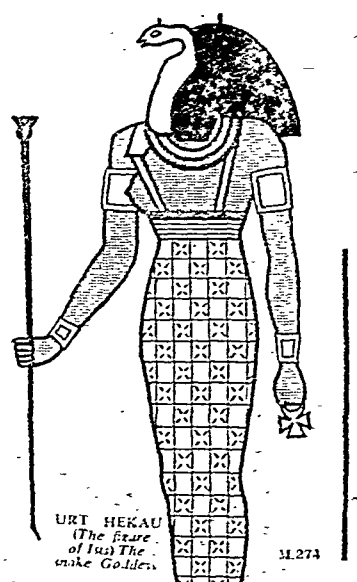
ALLEN & HANBURYS LTD., LONDON, E.2

Telephone: Bishopsgate 3201 (12 lines)

Telegrams: "Greenburys Beth London"

Further particulars and clinical sample will be sent post free on application.

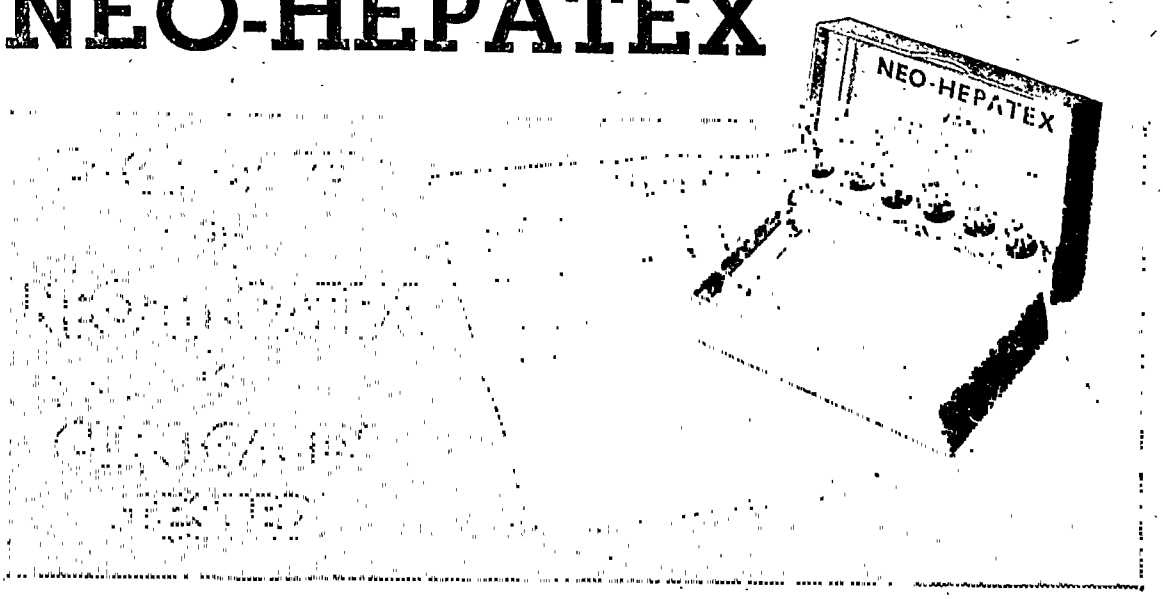
BEFORE AND AFTER OPERATIONS



THE use of "Ovaltine" before a major operation is of great service in helping to build up the system against the strain involved by operative interference. In abdominal cases especially, where a light and unirritating diet is necessary, the use of "Ovaltine" alone for a few days before the operation will be found sufficient to maintain the patient's nutrition at a sufficiently high level.

After severe operations, the regular use of "Ovaltine" is of the greatest service on account of its bland nature, its ready digestibility and its highly nourishing and sustaining properties.

"Ovaltine" is a complete food, composed of fresh, full-cream milk, eggs and malt extract, in the form of crisp granules which dissolve readily in milk to form a delicious beverage acceptable to the convalescent patient.



A liberal supply for clinical trial sent free on request.

Liverpool and London

Proved efficiency with *pleasantness*

In spite of its high germicidal efficiency (Rideal-Walker 3.0) 'Dettol' can be used at strengths impracticable with carbolic and cresylic antiseptics. It is non-poisonous, non-staining, pleasant smelling. It has been shown that when 30% 'Dettol' is rubbed into the hands and allowed to dry the skin remains insusceptible to infection by haemolytic streptococci for at least two hours unless grossly contaminated. 'Dettol' is also stable in the presence of blood, pus, faeces and other organic matter.

Obtainable from chemists in 1/- and 3/- bottles; and in larger sizes for medical and hospital use.
(These prices do not apply in the Irish Free State and Overseas.) *Samples and full information on request.*

'DETTOL' TRADE MARK THE MODERN ANTISEPTIC

'DETTOL' will be exhibited at the B.M.A. Annual Exhibition, Stand No. 20, Ulster Hall, Belfast, July 19th—23rd.

RECKITT AND SONS LTD. (PHARMACEUTICAL DEPT.) HULL. LONDON: 40 BEDFORD SQUARE, W.C.1

'CYSTAZOL'

A POWERFUL URINARY ANTISEPTIC

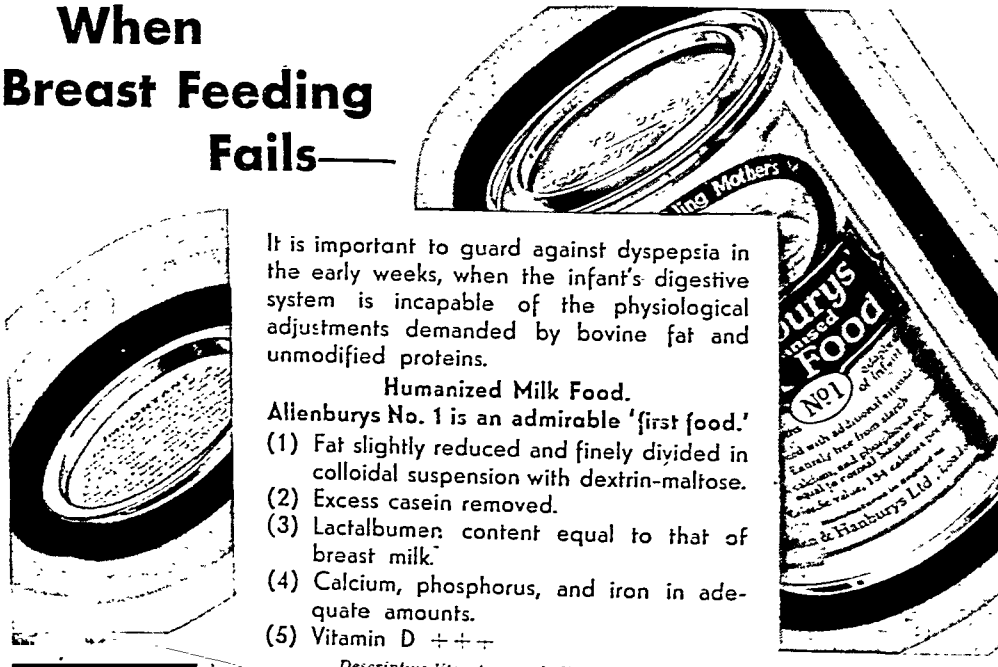
'Cystazol' is a combination of Hexamine with Sodium Benzoate: its action depends on the liberation of formaldehyde from the decomposition of the hexamine that takes place in the urine which has been rendered acid by the sodium benzoate moiety.

'Cystazol' is employed with advantage in cystitis, bacilluria of all types, pellagra, gonorrhœa and septic conditions of the urinary tract generally.

COMPRESSED TABLETS of 'Cystazol'

Supplied in bottles of 20, 40, 80, 160 and 500 (10 grain) tablets, at 1/6, 2/6, 4/6, 8/6 and 20/-

EFFERVESCENT GRANULES of 'Cystazol'



Supplied in bottles at 2/6 and 4/6.

Descriptive literature and clinical trial sample will be sent post free on application.

When Breast Feeding Fails—

It is important to guard against dyspepsia in the early weeks, when the infant's digestive system is incapable of the physiological adjustments demanded by bovine fat and unmodified proteins.

Humanized Milk Food.

Allenburys No. 1 is an admirable 'first food.'

(1) Fat slightly reduced and finely divided in colloidal suspension with dextrin-maltose.
(2) Excess casein removed.
(3) Lactalbumen content equal to that of breast milk.
(4) Calcium, phosphorus, and iron in adequate amounts.
(5) Vitamin D +++

Descriptive literature and clinical sample will be sent on application.

"The Vitamin B_1 activity is assured

by biological assay of *every day's output*"

So far as is known, there is only one food product for which such a claim, involving no fewer than 250 biological assays for Vitamin B_1 per annum, is or can be made.

Unnecessary? Consider this:

"*Unselected yeasts may vary tenfold in their vitamin B content*"—(*J. Nutrition*, 3, 257)

"*Unselected wheat germs may vary fivefold in their vitamin B_1 content*"—(*J. Hygiene*, 37, 303)

Statements as to the Vitamin B_1 potency of foods, etc., couched in general terms, are unacceptable for therapeutic purposes unless supported by (1) an assay of each lot manufactured (2) a guarantee that the potency will not diminish with the passage of time.

How then can the physician make sure that his patient receives, in a natural form, any desired amount of vitamin B? Only by prescribing Bemax.

BEMAX

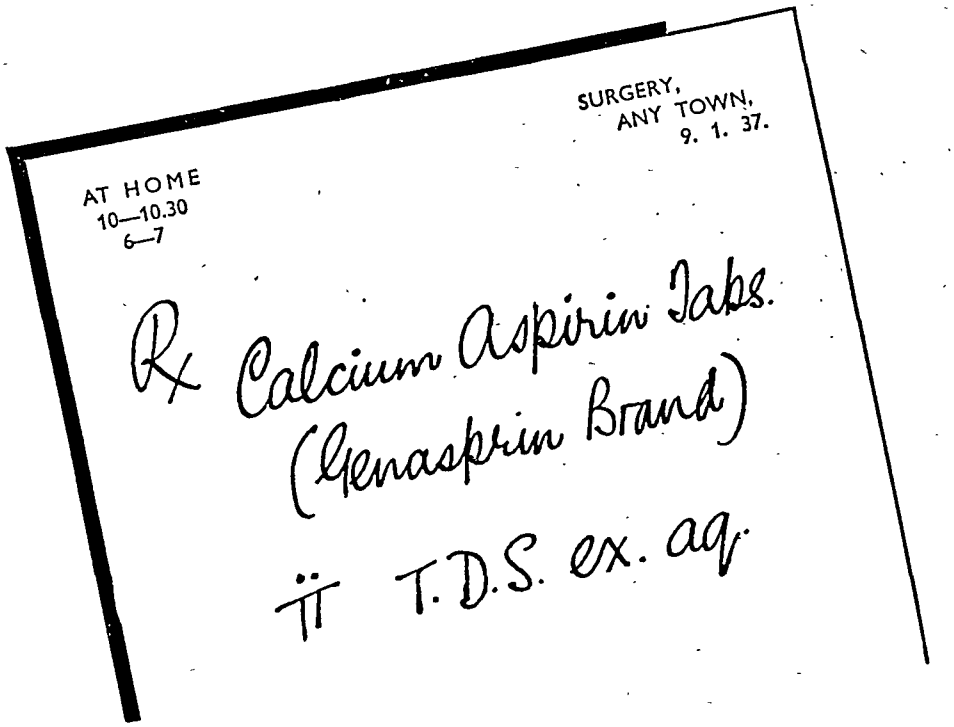
A unique natural source of accessory nutritional factors.

Vitamin B_1 — 400 International Units per ounce.

Vitamin B_2 — Flavin present.

Vitamin B_6 — (Anti-dermatitis) One of the richest sources.

Vitamin A—280 International Units (as Carotene).



Vitamin E—the richest natural source;

Phosphorus — 330 mg. per ounce;

Magnesium — 99 mg. per ounce;

Iron—3 mg. per ounce, and Copper =0.45 mg. per ounce.

THE BEMAX LABORATORIES, (Dept. B43), Upper Mall. London. W.6

STABILISED—SOLUBLE—NEUTRAL

As an analgesic and antipyretic, CALCIUM ASPIRIN (Genasprin brand) TABLETS possess all the virtues of purest aspirin without any of the latter's side actions.

Being neutral and soluble, CALCIUM ASPIRIN (Genasprin brand) cannot cause gastric irritation, acidosis or demineralisation.

In cases of calcium deficiency, pregnancy, lactation and growth, the value of CALCIUM ASPIRIN as against aspirin is clearly demonstrated.

Its low toxicity permits large doses and safe administration to children; in fact, it is now routine treatment for chorea in children and young people.

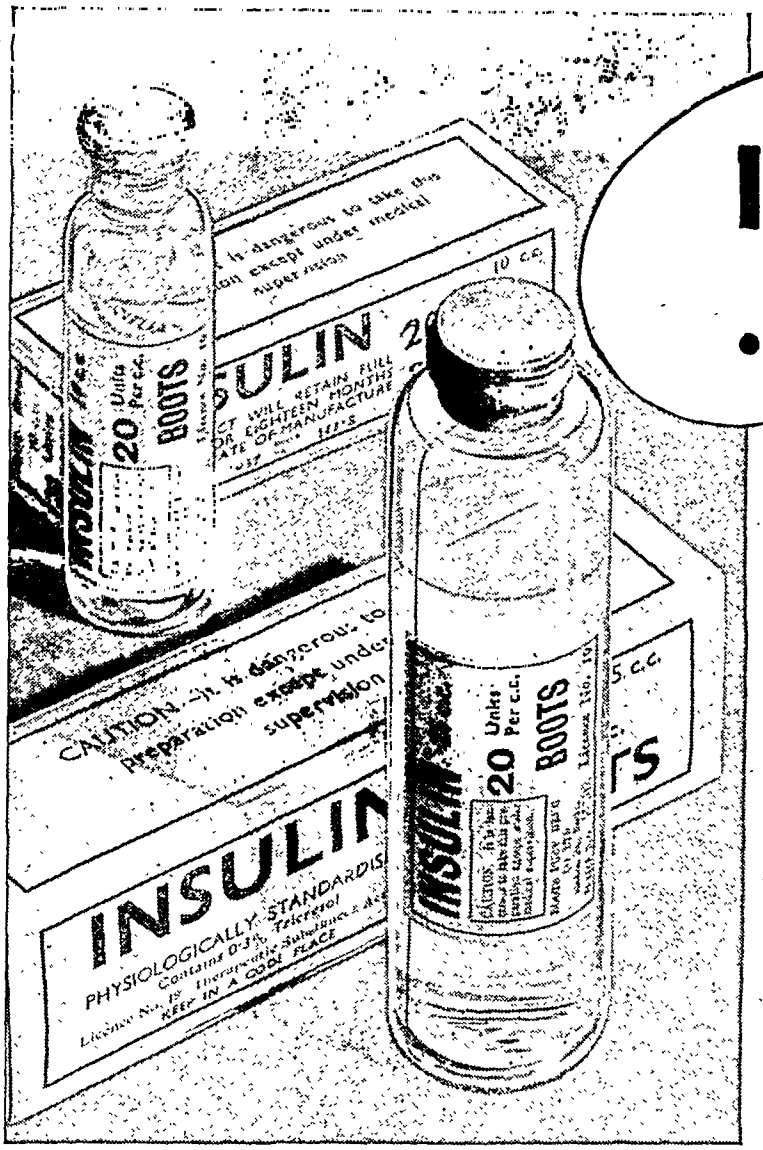
THE THERAPEUTIC VALUE OF THE BANANA

II. Gram-Positive Results



B. S. Kahn states that fructose is an exceedingly favourable medium for the growth of Gram-positive intestinal bacteria. He reports that infants fed on a milk mixture containing 5 per cent. of banana powder showed a conversion of the intestinal flora from an almost complete Gram-negative to an almost complete Gram-positive state.

If, as appears possible, this is due to fructose, it emphasises the use of the banana as an article of diet during treatment, but only of course when fully ripe, for it is then that the fructose percentage is at its highest. In the successful use of bananas in the diet of diabetics, the improvement of the fæcal flora has been assigned as this cause.

N.B. In the fully ripe banana the starch content is reduced to about 3 per cent., having been changed into soluble sugars. A banana is ripe when all green has disappeared from the skin and brown spots have formed upon the yellow surface.

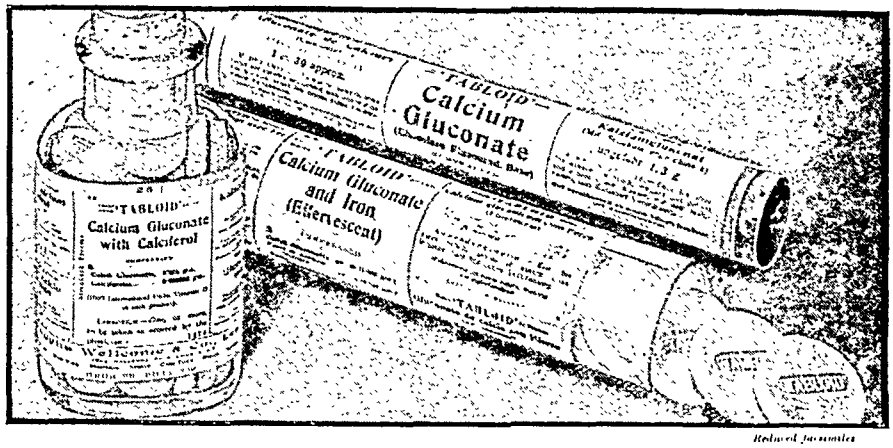
Anti-Dysentery Serum

Anti-Dysentery Serum is prepared from the serum of horses that have been highly immunized against *Bacillus dysenteriæ*. While much of the endemic dysentery of tropical and sub-tropical lands is caused by pathogenic amœbæ, epidemic dysentery due to *Bacillus dysenteriæ* occurs all over the world, and bacilli of the dysentery group are found also in asylum or institutional dysentery, in some sporadic cases of ulcerative colitis, and in certain forms of summer diarrhœa.



The content of Shiga antitoxin in Anti-Dysentery Serum can be determined and, in accordance with the requirements of the Therapeutic Substances Regulations, is stated in terms of an International unit.

Anti-Dysentery Serum (Multivalent) Shiga (5,000 units)
Flexner, Sonne, and Y (Concentrated)
In ampoules of about 10 c.cm., at 8/6 per ampoule.

Anti-Dysentery Serum, Shiga (10,000 units per ampoule)
at 8/6 per ampoule.

HEREDITY AND CONSTITUTION IN THE AETIOLOGY OF PSYCHIC DISORDERS*

BY

PROFESSOR ERNST KRETSCHMER

Director, Psychiatric and Neurological Clinic, Marburg University

The significance of heredity and constitution in psychic diseases is not limited to those groups of mental disorders which, in the narrower sense, are usually termed "hereditary diseases," but reaches far beyond them. Conversely, the diversity of causes in hereditary diseases is by no means exhausted by what we call heredity and constitution.

The Three Main Groups of Psychoses

Let us, to begin with, concentrate on these hereditary diseases in the narrower sense of the term—that is to say, mainly on the three main groups of the manic-depressive, the schizophrenic, and the epileptic diseases. If in these cases we base our investigations only on the psychoses themselves, then the genetical tables will be reminiscent of completion-test texts. We find strong evidence of the workings of heredity; we find psychoses of a similar nature repeatedly cropping up in family trees. But that alone does not suffice to explain why they take their particular position in the tables, why they appear in one place and disappear in another. An essential advance in our knowledge has been due to the fact that these psychoses are not inherited intermittently as an isolated special factor by themselves, but that the relations between the various cases of psychosis in a family can, to a certain extent, become discernible, phenotypically, as variations of the personality. To-day, therefore, we no longer study hereditary diseases merely under the aspect of the relations of psychosis to psychosis, but to an ever-growing extent within the great framework of the psycho-physical constitution as a whole, thus bringing personality and psychosis into close relationship.

We had, first of all, ascertained that subjects who develop schizophrenia, manic-depressive disturbances, or epilepsy have no random psychic make-up. In fact, each of these hereditary diseases develops on the foundation of certain personalities and families of a definite coloration. These families have a larger proportion of personalities of a peculiar shade who, without being ill themselves, do exhibit a biological make-up, both in bodily characteristics and in the finer traits of character and temperament, which approaches the characteristics of personality we find in mental invalids. According to their classification in their respective hereditary diseases we term them schizoid, cycloid, or epileptoid psychopathies. Thus each of these hereditary diseases is surrounded by a sphere of certain specifically characteristic hereditary constitutions and characters. Once these constitutions have been recognized the hereditary diseases no longer appear as chance phenomena. A complicated network of relations is unfolded before us which leads from certain healthy temperaments through certain nervous and psychopathic forms of constitution, and on to the gravest forms of hereditary diseases. Within this network one may regard the hereditary diseases proper as points of utmost concentration of a specifically directed form of degeneration. Thus, lastly, the hereditary diseases do not spring only from the propagation of those afflicted by them, but probably to a far greater extent through the medium of schizoid, cycloid, and epileptoid kin, and through combinations of inheritance. There are two ways of visualizing this genesis: either as a strong accumulation of homogeneous factors, as occurs in inbreeding (for instance, in the single or repeated mating of highly schizoid partners), or by way of an endogenous or exogenous lesion, in itself uncharacteristic, which is added to such a combination, whereupon at this genetic stage the hereditary disease is developed which is appropriate to the constitutional make-up of the particular family—that is to say, in an epileptoid family epilepsy, in a schizoid family schizophrenia, and so on. This latter form of origin is the more probable.

Physique and its Relation to Temperament

With these first principles well established we next proceed to make a more exact study of the forms of human constitution, including healthy subjects. As it happens, one can dispense with the intermediate link of the hereditary diseases altogether, and simply investigate the forms of human physique in direct relation to their psychology and their types of physiological responses. We then discover that the temperaments which we had termed "cyclothyme," after our primary survey of the hereditary manic-depressive disorders, are simply the normal temperaments of people with pyknosomatic physique, whilst the schizothyme temperaments occur in the first place in the leptosomatic types. The temperaments of athleticosomatics actually show some affinity with certain personality types in the epileptic group, to which they contribute a considerable contingent, but a uniform relationship cannot be directly established. Such temperaments can, however, be well differentiated and described in a direct manner in healthy subjects. We have termed the temperaments of the athleticosomatics viscous temperaments. Many smaller physique-groups also have their temperamental characteristics—for instance, the eunuchoid type, the pituitary type, and the infantile type, to whose relation to the hysterical group we shall refer later. The three main normal temperament groups, which have been differentiated in accordance with their physical habitus, lend themselves to direct observation and to methods of investigation by questionary, but especially to the experimental psychological approach. Thus one arrives at certain simple psychological building-stones of the structure of human personality which, for the moment, cannot be further reduced, and which correspond

* One of three lectures given at the Tavistock Clinic in April.

with physique. We call these "radical forms of the personality." We are now working with these radicals, to which we are beginning to reduce the temperamental types and from which, again, the great temperamental groups can be correspondingly built up.

Diagnosis of the Endogenous Psychoses

If we now pass from the general biological approach to the consideration of special psychopathological problems we find that the diagnostics of the endogenous psychoses are beginning to be considerably transformed in the light of these recently acquired additions to our knowledge. However, the three principal types of hereditary psychic disease, the schizophrenic, manic-depressive, and epileptic, are retained as before. In fact they become paradigms of certain fundamental hereditary characteristics in the human personality which obtain equally in the realm of normal biology.

But as soon as we consider clinical diagnostics in particular we find that the three great morbid clinical pictures, in their present very comprehensive form, contain extremely heterogeneous elements. If, for example, a pyknosomatic subject develops a schizophrenia-like psychosis his schizophrenia will on the whole differ essentially from the schizophrenia of a leptosomatic. Usually it will have a differently coloured semeiology, a different age of onset, and a different development and prognosis. The pyknosomatic who happens to trespass into the schizophrenic field usually develops his illness later in life and exhibits more periodic or paranoid forms, which are less destructive to the personality. Further, the prognosis in his case is altogether more favourable. The athleticosomatic, eunuchoid, obese, and other types also exhibit specific varieties of schizophrenia.

In the light of constitutional biology even so simple a picture as that of depression reveals a rich abundance of heterogeneous patterns. When a schizoid personality develops a depressive state then its coloration, its more subtle psychological structure, its accompanying bodily symptoms, tempo, and curve of development, differ so widely from those occurring in a cyclothyme-pyknosomatic subject that one almost shrinks from describing both by the term "depression." In this case, in fact, the common term may serve to obscure rather than illuminate the issue. In any case nowadays one can hardly bring oneself to include a melancholia which is overloaded with schizoid constitutional features in the manic-depressive group if the term "circular," or "manic-depressive," is to retain any true biological meaning.

So when we now study the relation between constitution and hereditary disease we shall no longer—as formerly of necessity—concern ourselves purely statistically with the relative correspondence; for instance, of leptosomatic physique or athleticosomatic physique with schizophrenic, manic-depressive, or epileptic psychosis. As it happens, even these summary statistics, computed from the international material of numerous research workers and covering over 8,000 cases, reveal a clear and positive correlation. But the degree of disparity in the results of the various investigators hardly tends to point to genuine discrepancies in their material, but rather to reveal how many or how few heterogeneous factors bearing on psychosis the various investigators have included in their clinical diagnoses, which may be perfectly correct according to older psychiatric standards.

However, we can now venture to reconstruct the system of hereditary psychic disorders step by step, analysing their finer structure under the aspect of psychophysical constitutional biology. This diagnostic method, which is based on true constitutional biology and which at the same time takes stock of exogenous causal factors, is of course far more complicated. It leads to a larger number of overlapping types and subgroups, but both prognostically and therapeutically it is much more reliable and successful.

This new psychiatric approach to the problem of hereditary mental disorders, which is influenced by constitutional-biological considerations, is of far-reaching significance to pure science, characterology, and clinical diagnosis; it also affects the prognostic and therapeutic aspects of clinical psychiatry. From the point of view of eugenics, in its negative (that is, its eliminatory) aspects, this extension of our knowledge of constitution does not materially affect our fundamental position—namely, that as a rule the carriers of serious hereditary disorders, both in their own interests and in those of society, should have no offspring. This principle holds good whether we choose to classify hereditary diseases under a few main heads (as did Kräpelin), or whether we prefer to differentiate them more thoroughly with the aid of constitutional biology. For more subtle eugenic problems, however, especially when we are called upon to advise both the healthy and those who exhibit psychopathic traits either in their person or their inheritance as to suitable marital partners and the likelihood of their producing healthy stock, our knowledge of constitutional biology cannot be sufficiently thorough and detailed. Great tasks are yet awaiting us in this field, and constitutional biology will be called upon to play a decisive part.

Exogenous Contributory Factors

Our approach is still further widened owing to the fact that in dealing with inherited disorders we need to consider not only inheritance itself (although it is admittedly the chief causal factor, which therefore rightly governs our practical outlook in matters of eugenics), but also the various exogenous contributory causes, which may be reactive, infective, or toxic; endocrine factors must also be borne in mind. For if only 1 per cent. of the total causality is lacking, then the psychosis will not manifest phenotypically; and the subject of morbid inheritance will remain a latent carrier throughout his life. This "multidimensional" approach has its greatest bearings on therapeutics. As clinicians we no longer regard hereditary diseases in individual cases as the working of inexorable fate. If we tackle the contributory causes, such as have been mentioned above, a psychosis often lends itself to cure. These considerations are supported not only by clinical experience but also by theoretical genetics, as, for example, Luxemburger's work on the occurrence of schizophrenia in monozygotic twins, carried out at the Rüdin Institute.

Clinical observation shows us that even so simple a psychiatric picture as depression occurs only in a minority of cases solely as a result of hereditary factors comparable to the ringing of an alarm clock which is mechanically set to go off at a certain time. Even in cases of powerful morbid inheritance many contributory causes are, as a rule, required to bring the depressive predisposition to the surface. There are, for example, certain infectious diseases, such as ordinary influenza, which can activate depression in predisposed subjects. The weather, and ordinary climatic conditions, may give rise to violent shifts of mood; a southern gale can depress persons with certain constitutions to the verge of suicide. There are people who can only live in certain climates, who in other climates are continually subject to depression.

Incidentally, similar phenomena occur in the field of epilepsy. There are epileptoids who develop tropical frenzy on their first oversea trip and who from then onwards exhibit episodic disturbances of consciousness even at home. People with the depressive predisposition are especially susceptible to endocrine fluctuations. The climacteric releases a variety of depressive states; an appropriate endocrine treatment may remove them. Many women become depressed in pregnancy or parturition, and sometimes only in such circumstances. In early cerebral arteriosclerosis many pyknosomatic cyclothymes exhibit depressions which can be counteracted by vascular remedies. Powerful experiences and reactive causes may lead to depressions, especially when they occur coincidently with physically determined depressive factors in a person who is constitutionally predisposed thereto. As the result of this refinement of the analysis of the causal factors in every variety of depression, which we owe to the multidimensional approach, and the consequent attempt to tackle causes therapeutically, the group of depressions which may be regarded as purely endogenous has diminished progressively. Strictly speaking, there is no antinomy and no defined borderline between hereditary and exogenous depressions; actually the various causes overlap to such an extent that one should often speak only of "mainly endogenous" or "mainly reactive" depressions. The evaluation of hereditary factors must, however, be taken into account whenever eugenic as opposed to simple therapeutic issues are involved.

Overlapping of Hereditary and Exogenous Causes

In epilepsy this overlapping of hereditary and exogenous causes is even more in evidence, and the role of severe external insults, such as cerebral trauma or alcohol, in the origin of epileptic fits is uncontested. Besides, reactive factors, psychophysical exhaustion, and endocrine disorders are by no means without importance in certain kinds of epilepsy. Here, again, one must beware of too sharp a distinction between "genuine" and "symptomatic" epilepsy. Even in the genuine cases "multidimensional" release mechanisms can frequently be traced; and, conversely, hereditary factors often contribute to the epilepsy following severe head injuries.

The hereditary factor is probably most important in schizophrenia; but even here Luxemburger's work on monozygotic twins points to the existence of contributory exogenous causal factors, apart from heredity, in about one-fourth of all cases. This aspect of the causal factors becomes far more complicated when we examine the border-zone of schizophrenia—for example, puerperal and infective psychoses with schizophrenic features or, on the psychogenic side, the so-called "schizophrenic reaction type." So far as the psychic causes are concerned it is worth noting that by no means all psychic traumata are equally likely to release psychoses in persons with a schizophrenic make-up. Thus the effect of factors threatening life—fright, fear, strain—is small on schizoid constitutions; otherwise one would have observed an enormous rise in schizophrenia during the war, which was by no means the case. Schizoids are comparatively immune from all these groups of experiences; probably this is in some way connected with their natural disposition towards a stoical attitude to life. On the other hand certain schizoid constitutions are highly susceptible to erotic and ecstatic religious influences. I have occasionally observed the acute onset of katatonia in which the religious note was consistently sounded immediately following revival meetings. Similarly, there exists what one might term "engagement-katatonia," which may follow on intense erotic experiences of an ambivalent nature. It is noteworthy that these two types of experience may not only release acute katatonia but they also still further reveal the deep psychology of many schizophrenics. Both are closely interrelated, so that love thoughts may at a certain degree of intensity suddenly turn into religious ideas, or religious ecstasy may stimulate and inform an erotic experience.

If we consider all these clinical facts in relation to the release of certain psychic-reactive and also toxi-infective cases of schizophrenia we find that they fit in well with the results of genetical research and that the secondary causes, which according to research on twins we must hold responsible for a substantial number of schizophrenic cases, are actually accessible to careful clinical observation.

A twofold task for psychic hygiene follows from these considerations. The first and foremost is to prevent by way of eugenics the inheritance of endogenous psychoses. But where this method fails the psychosis in the life of the hereditarily tainted individual can frequently be prevented from later appearance by prophylaxis; or it can be cured after its appearance if we devote careful study to the variety of the causal factors which, together with inheritance, are responsible for the onset of an unequivocal psychosis.

The Exogenous Psychoses

But if we want to realize the significance of constitution and heredity in its full scope we must turn for a moment to the seemingly opposite end of the scale of the psychic disorders—namely, the *exogenous* psychoses. In such disorders, which can be exemplified by general paralysis and alcoholic psychosis, a non-hereditary, non-constitutional noxa enters the organism from without and is unquestionably the main cause of the illness. Is the inherited constitution negligible in these cases? And can the many variations in the clinical picture and their mode of progress be explained simply by exogenous determinants—for instance, by the existence of different varieties of spirochaete? According to our more recent investigations this is definitely not the case. The hereditary constitution plays a considerable part, too, in disorders that primarily are determined exogenously, not only in the production of semeiological nuances but also by affecting the whole progress of the disease. For general paralysis and puerperal psychosis this fact has been established by my collaborators Westphal and Römer, and for alcoholic psychosis by Pohlisch.

In dealing with the alcoholic psychoses Pohlisch mainly stressed the constitutional differences found in those suffering from delirium tremens and alcoholic hallucinosis. These varying clinical forms are by no means due to different varieties of alcohol; they represent different types, different constitutions, which develop delirium or hallucinosis as the case may be. Among the deliriants no fewer than 55 per cent. were found to be pyknosomatic and 64 per cent. were temperamentally markedly cyclothyme; only 1.8 per cent. showed asthenic physique, and only 3 per cent. were temperamentally schizothyme. With hallucinosis the ratio was reversed: schizoid temperaments were clearly predominant (almost three-fourths of all causes). Correspondingly, the delirium tremens series contained many socially well-adapted, efficient individuals without personal or hereditary character defects. Patients suffering from alcoholic hallucinosis, on the other hand, were frequently of the unstable, asocial, and nervous type—not far removed from schizophrenics.

Similarly it is probable that the alcoholic disorders which occur in persons with the epileptoid constitution could be shown to link up with epileptic psychosis proper.

It is important to realize in this connexion that the constitutional factor in the exogenous psychosis does not merely effect a slight variation of the symptomatic picture in accordance with the patient's personal peculiarities—this would follow as a matter of course—but that it is an essential determining factor in the very structure of the psychosis, a factor which does not merely colour the symptomatic picture but which determines the whole course and termination of the disease. The psychological reasons for taking to drink vary in accordance with a person's constitution; the alcoholic disorder with which he is faced is correspondingly different, and the prognosis is different. These considerations also affect our approach to the biological and eugenic aspects of alcoholism. Since, according to Pohlisch, alcoholic delirium, in contrast to the other alcoholic psychoses, seldom occurs as a familial disorder and frequently crops up in constitutionally healthy individuals, it should be regarded as of less serious import than the other psychoses when we are called upon to advise in matrimonial problems.

Influence of the Constitution

Constitution plays no less important a part in the determination of the reactive neuropsychoses, psychogenic conditions, psychoneuroses, hysteria, obsessional neurosis, and paranoid states. Although we are frequently able to cure them by psychotherapy we must never forget that successful psychotherapy just as often depends on problems of personality-structure as on experience and environment. The structure of personality is in its essence constitutional and inherited. In our treatment we exert a formative influence on it. Often external experience is not so much the real cause of a neurosis; it is rather a flame which ignites the inner typologically determined mass of conflicts within the personality. Practical psychotherapy has shown us that in the origin of the neuroses definite constitutional elements play a part—for instance, minor developmental arrests, especially those occurring during puberty and in the immediate post-pubertal period.

In hysteria, for example, the constitutional predisposition is by no means limited to what is generally termed "nervousness." Certainly all hysterics exhibit autonomic nervous anomalies; their reflex and semi-reflex reactions are highly labile and are easily deflected. But this is not the whole story so far as the specific hysterical predisposition is concerned: there are innumerable people with a labile autonomic nervous system, but few necessarily consult a doctor, and among them only a small number are hysterics.

Furthermore, in hysterics our methods of investigation reveal a mass of minute constitutional sexual anomalies which, if we regard the personality in cross-section as it were, appear as stigmata at the level of physique and character. These anomalies are perhaps even more conspicuous if we regard the personality, so to speak, lengthwise—that is, as a life curve—when they become clearly apparent as developmental checks and uneven rhythms in the pubertal and post-pubertal periods. It is these anomalies which form the other half of the constitutional predisposition to hysteria mentioned above. It is noteworthy, however, that extreme degrees of developmental arrests such as are associated with endocrine disorders and generalized infantilism do not as a rule give rise to hysteria; the more usual resultant picture is one of more generalized psychological inferiority uncomplicated by psychic conflicts. However, it is these *partial* "infantilisms" and "juvenilisms" which give rise to endopsychic tension and ambivalence and prepare the way for conflict formation, in that they weaken a person's resistance to the effects of traumatic experiences and situations.

These constitutionally predetermined irregularities of development are apt to lead to conflicts with the outside world and its demands that cannot be resolved in the way in which a normally constituted individual would take them—that is, in his stride. Hence the constitution creates its own conflicts in relation to experience, to which it then, in turn, reacts pathologically. Here again the diagnosis of inherited predisposition in neurosis by no means impedes our practical work and our therapeutic success. On the contrary, it increases our ability to recognize the chief foci of endopsychic conflict and the means by which they can be overcome. So far as mental hygiene is concerned prophylaxis by means of eugenic measures applies less to the neuroses. On the other hand, the recognition of the constitutional elements in psychogenic disorders offers wide possibilities for prophylactic treatment by way of the medical-educational training of the personality.

THE PHYSIOLOGICAL BASES OF NUTRITION*

BY

STUART J. COWELL, M.B., F.R.C.P.

Professor of Dietetics, University of London

It would not be fantastic to claim the greater parts of the fields of biochemistry, physiology, pathology, and clinical medicine as the legitimate province of the modern science of nutrition. As our knowledge of fundamental living processes increases, it can be seen more and more clearly how chemical and physical changes are not only responsible for determining the normal physical development and the maintenance of the organism in a state of equilibrium with its environment, but are equally associated with those special reactions to environmental stimuli which we recognize as signs of diseased states. This well-recognized conception implies that development, the maintenance of health, and the disturbance of health depend on the orderly or disorderly function of metabolic processes which can legitimately be held to imply, respectively, perfect or imperfect states of nutrition. It is conceivable, or rather probable, that with further advances in knowledge most of the diseased states which we now recognize will be definable in terms of definite disturbances of metabolism or nutrition. The scope of the B.M.A. Section of Nutrition would under these conditions be wide enough to cover a large part of the field of medicine; and indeed it is already capable of so doing, as the President of this Section was able to prove for us in his opening address last year. For practical convenience, however, at the present time it seems politic to limit the sphere of our interest mainly to those nutritional processes which are known to be more or less directly related to the intake or absorption of food. In regard to the subject under discussion to-day, for example, it would be within the scope of the title to include the physiology of respiration and excretion, muscular exercise, personal hygiene, and so on. Actually all the formal contributions to this discussion will be concerned with dietary constituents and their contribution to nutrition.

* Read in opening a discussion in the Section of Nutrition at the Annual Meeting of the British Medical Association, Belfast, 1937.

Awakening of Interest in Nutrition

When I was honoured by receiving an invitation to open this discussion the title had already been chosen, and it was clearly the wish of the officers of the Section that the opener should expound the views of modern experts on the dietaries considered likely to promote optimal physical development and maintenance of health among Western peoples—views which have recently been crystallized by a representative committee appointed by the Health Committee of the League of Nations. This is not the occasion for detailing the history of the inception of this committee of experts, but we may be permitted to remind ourselves of the developments which led ultimately to the publication of the committee's practical recommendations.

There is no doubt that it has been the more accurate knowledge of nutritional processes gained from the study of experimental animals in the laboratory which has been primarily responsible for the awakening of interest in the problems of human nutrition. Following the lead of such animal experiments, it has been shown that the general principles which have emerged from the laboratory are on the whole applicable to human beings. Some years ago it was clear to those who were actively engaged in this work that the knowledge which had already accumulated ought without delay to be made available for the securing of better nutrition for the masses of mankind. The recent world-wide trade depression, with its accompanying unemployment and poverty, provided the opportunity for interesting large sections of the world's populations in the question of nutrition and malnutrition. Government departments began to be conscious of the fact that they had some responsibility in the matter of encouraging the people entrusted to their care to secure for themselves and their families the largest measure of health and well-being which right feeding could give them. In the meantime the Health Department of the League of Nations had been interested in the application of the newer developments of the science of nutrition to the problems of feeding human beings, and was busy collecting information regarding the relation between nutrition and states of health and disease, and regarding the existing evidence of malnutrition among different races of mankind. The resulting admirable report by Aykroyd and Burnet rightly attracted a considerable amount of attention, and did a good deal towards preparing public opinion for the conclusions of the special committee of experts which the League of Nations appointed to consider the practical question of recommending diets calculated to secure good nutrition in human beings. The first report of this committee was published in 1935 under the title of our present discussion; the report was revised and reissued in 1936. This final version will be the main theme of my contribution.

Practical Aspects of the Nutrition Problem

I propose to limit my observations, as the League committee has done, to certain practical aspects of the problem of human nutrition. The main questions I wish to discuss are: What can we hope to accomplish by any dietary recommendations that we may feel justified in making?; and, What diets are most likely to secure the desired effect?

Only tentative answers can be given to these questions: we cannot always wait for full knowledge before planning a course of action. The primary aim in making any dietary recommendations is, except possibly in rare instances of medical emergencies, to secure the best possible state of nutrition which a suitable combination of foods can bring about. The term "best possible" is used rather than "optimal" for the reason that hereditary defects, previous disease, or deleterious environmental factors may prevent a perfectly good diet from exercising its full nutritive effect, as we shall no doubt learn from the contributions of Dr. Brock and Dr. Spence. The fact that so many private individuals and official committees have of late considered it advisable to make dietary recommendations implies that in their opinion the state of nutrition of a considerable proportion of our existing populations is not as satisfactory as it might have been under the influence of an ideal dietary. And there is much evidence to support this opinion. There is, for example, no doubt that the physical development of very large numbers of our children could be improved by better feeding during the whole period of growth. The milk-feeding tests which have been carried out in many different countries have shown that the mean rate of growth of any large group of children can be accelerated by regular supplements of this valuable food. Sufficient time has not yet elapsed for information to be available regarding the ultimate effect of such accelerated growth in the final state of development. The experience of most of those who have been engaged in controlled feeding work with laboratory animals has been that diets which promote the most rapid growth in early life maintain the animals in the most vigorous health in adult life. It is, however, interesting to note that Dr. Hayward of Cornell University found he could prolong the life of rats by stunting them in early life, a result apparently in direct contradiction with the experience of Professor Sherman, whose rats survived to old age better when they were given diets which promoted the most rapid rate of growth.

The skeletal development of children could without doubt be improved by better feeding. While the propaganda of the last fifteen years has resulted in a considerable diminution in the incidence of the grosser manifestations of rickets, there are indications that minor skeletal defects due to suboptimal bone calcification are still common. Of equal or even greater importance is the fact that the development of the teeth is undoubtedly handicapped in the majority of our children by suboptimal nutrition in early life. The relation between diet and the development and maintenance of sound teeth is of paramount importance, and I shall refer to it again in a few moments.

Before leaving the question of diet in relation to development I would draw your attention to certain less gross effects of faulty nutrition in the matter of physical development. Under this category might be included the failure of the haemoglobin-producing mechanism caused by iron deficiency in childhood. As far as is known this nutritional fault is completely reversible, but there is evidence that other faults may not be completely reversible—for example, the abnormal development of the gingival epithelium in young dogs, described by M. Mellanby as arising from deficiency of vitamin A. This made them susceptible to pyorrhoea in adult life even if adequate supplies of vitamin A were given for long periods after growth had ceased.

Effects of Suboptimal Diets

The extent and perfection of physical development is not the only benefit to be expected from proper feeding. The question of the maintenance of a state of health and full vigour is becoming more and more widely recognized as one in which right feeding must occupy a prominent

position. There is no time for me to go fully into the various ways in which suboptimal diets may affect the health. Frank deficiency diseases due to a low intake of mineral elements and vitamins, and possibly good protein, are by no means rarities in the British Isles. In many parts of our Empire they are far too common, as is now being made abundantly clear by the investigations which are taking place in Ceylon, India, Africa, and Australasia. How far minor degrees of specific deficiencies are responsible for lessened vigour and vitality, and lowered resistance to infections and degenerative diseases, is still largely a matter of conjecture, but steps are being taken to fill in this gap in our knowledge. Clinical and biochemical tests are now being used—for example, in an attempt to recognize the earliest signs of deficiency of vitamins A, B, and C—and the results may enable more accurate estimates to be made of the effect of suboptimal diets on the general state of health.

Questions which have attracted a great deal of attention and which still require much further investigation involve a more exact understanding of the relation between faulty nutrition and infection, including the response to established infections of an acute and chronic nature as well as the incidence of infection. There is much evidence that common diseases and disorders of the alimentary tract may be related to faulty feeding, though the mechanisms by which they are brought about remain obscure. The subject of dental caries deserves special mention. Though there is still much dispute as to its cause, all are agreed that it should be largely controllable by suitable feeding, and the kinds of diets advocated by the protagonists of the opposing views concerning its aetiology are not in practice very different. Further investigation is obviously desirable, but in the meantime it should be possible to reduce enormously the amount of dental decay in the next generation by securing as perfect a state of nutrition from the pre-natal period onwards as existing knowledge will permit.

Steps to Secure Improved Nutrition

This very sketchy outline of some of the results which might be expected to follow a general improvement in the state of nutrition of the masses of mankind must suffice for the moment. Our President gave us last year a much fuller and more complete account of the relation between faulty nutrition and disease. Time compels me to turn now to a consideration of the steps which should be taken to secure the desired improvement in the state of nutrition. The main lesson we have to learn from the fundamental research work of the present century is that optimal nutrition depends on the liberal supply in the diet of every food-component which cannot be manufactured in the body from some other constituent of food, as well as on an adequate allowance of calories and utilizable nitrogen. The term "liberal" which I have just used in reference to the supply of essential food constituents was deliberate. In some quarters there is a tendency to assume that an adequate supply of these constituents is one which prevents the appearance of gross signs of deficiency diseases, whereas there is plenty of experimental evidence to show that improved states of nutrition can be secured by increasing the intake of such constituents above the level at which mere protection from recognizable deficiency symptoms occurs.

Though man's requirements of many of the vitamins and mineral elements can be stated to-day with a fair measure of confidence, he would be a rash man who would attempt to devise synthetic diets containing measured quantities of all known food constituents and guarantee that perfect nutrition would follow their consumption. We are not in a position yet to define the exact chemical composition of an ideal diet, and it is surely wise, therefore, to guard against any possible deficiencies by including in our ideal diet liberal supplies of those foods which experiment and experience have shown to be most likely to contain any unsuspected essential constituents, as well as those foods which have already been shown to be rich in essential food factors.

Not only should the ideal diet consist of suitable quantities of the right kinds of food, but the foods of which it is composed should be produced under conditions which ensure that it is richly supplied with the essential constituents it ought to contain. This applies to foods of both animal and vegetable origin. More and more information is coming to hand regarding the variations in the concentration of important dietary constituents in foods produced, transported, and stored in different ways. It is obviously not safe at present to assume that a diet is adequate in every respect if it contains the bare minimum of essential components calculated from chemical or biological assays carried out on foods produced or kept under varying conditions. The wise course is to include in our ideal diets liberal supplies of those foods which are to be relied on to secure the necessary quantity of essential food constituents.

Practical Recommendations

This brings us to practical recommendations for securing optimal nutrition. We shall lay stress on the provision of a liberal supply of foods rich in vitamins and in mineral elements, especially calcium and iron in an assimilable form—that is, foods which have lately received the name "protective." This is the essential feature of the diets recommended by the League of Nations Commission. Its corollary is a corresponding decrease in the amount of inert if not actively harmful foods such as refined sugar and cereals. Adequate provision of calories and protein is by no means to be neglected, but in our own country this is not such a pressing problem. The protective elements of our diet can most easily be secured by increasing the consumption of milk, especially safe liquid milk, and other dairy products, all kinds of vegetables, especially green vegetables including salads, eggs, fat fish, and liver. In a diet planned on these lines the proportion of cereals will be reduced. The question of the relative merits of refined and whole-grain cereals was not treated at all exhaustively by the Commission, who supported the proposal that part of the cereal eaten should be lightly milled. It seems possible that the best practice would be so to increase the proportion of starch eaten in the form of vegetables, especially potatoes, that a comparatively small amount of cereal would be eaten, of which the bulk should be lightly milled so as to increase in the total diet the quantity of B vitamins and assimilable iron.

Diets for Children

The Commission rightly stresses the extreme importance of providing the best possible diets throughout the whole period of growth. This is, of course, one of the reasons why the diet it recommends for pregnant and lactating women contains such a large proportion of protective foods. There is no need to dwell on the special dietary requirements of mothers, since this question was fully discussed at yesterday's meeting. But a few words must be said regarding the proposed diets for children. Their special feature is the high proportion of the total energy

value contributed by protective foods, which is largely due to the inclusion of a liberal allowance of milk throughout the whole period of growth. The diets for children between the ages of 1 and 3 contain rather more than three-quarters of their total calories in the form of protective foods; those for children between 3 and 7 contain rather more than two-thirds, and this proportion is diminished in the pre-adolescent age to rather less than one-half. This insistence on a high proportion of protective foods is really the essence of the scheme for securing good nutrition. It runs directly counter to the attitude not infrequently adopted in some quarters that as long as a diet contains enough of the essential food constituents to prevent symptoms of deficiency diseases there is no point in worrying about its make-up.

There was recently published by Mr. Rowntree in his book *The Human Needs of Labour* a dietary scale, "representing a standard below which no class of worker should be forced to live," for a family of man, wife, and three children under 14. I made a rough analysis of this diet, and calculated that even if each child received more than his share of the protective foods in proportion to his man-value equivalent, less than one-quarter of his food intake would be derived from such protective foods—and even then more than half of the protective foods would be composed of cheap cuts of meat and condensed skim milk. It is true that even a diet such as this compares most favourably with diets consumed in many parts of the world. To take just one instance, Dr. Aykroyd has recently carried out a survey of diets in South Indian villages. Among the poorest group the diet averaged 1,664 calories per unit of man-value, and 95 per cent. of the calories were derived from cereals. The children forced by poverty to live on such diets showed only too frequently gross manifestations of deficiency diseases and general malnutrition, while the children brought up on the diets suggested by Mr. Rowntree might escape without immediate obvious symptoms of food deficiency other than slight indications of rickets, poorly developed teeth susceptible to decay, and a general physique below their potential optimum. All who have tried to put into practice the modern principles of nutrition, whether on experimental animals or children, would agree, I think, that it is worse than useless to lay down as a standard any diet which is likely to produce imperfect development and suboptimal states of nutrition. It is true that mere pious expressions concerning the make-up of the ideal diet will not enable the poor to buy the food best calculated to promote perfect nutrition. Fixing a dietary standard which approaches the ideal for promoting good nutrition at least draws attention to the urgency of the practical problem of trying to bridge the gap between the ideal and the actual, whereas an admittedly low standard merely encourages complacent individuals and authorities to continue their policy of *laissez-faire*.

Our discussion is concerned with the physiological, not the economic, bases of nutrition, and it would be out of order for me to pursue further the sociological and political implications of dietary standards. It will suffice to remind you that the Health Organization of the League of Nations is deeply concerned with the economic, agricultural, and political problems involved in attempting to supply a sufficiency of health-promoting foods for the populations of mankind. Our own Government Departments are already tackling the same problem, and a perusal of the first report of the Ministry of Health's Advisory Committee on Nutrition will show that these practical aspects of the situation are receiving serious attention.

THE ROLE OF HETEROPHORIA IN BINOCULAR DISHARMONY

WITH SPECIAL REFERENCE TO AIR PILOTAGE*

BY

WING COMMANDER P. C. LIVINGSTON,
F.R.C.S.E., D.O.M.S., D.P.H., R.A.F.
Consultant in Ophthalmology, Royal Air Force

To confine this paper entirely to the domain of the air would be like writing the final lines of a book without considering the framework of the first chapter. The condition that we style heterophoria must be age-old, but the contest for mastery of the air is, within practical limits, an event of our generation. Racing through space does not itself produce heterophoria, but heterophoria may severely affect safe aerial manœuvre. Therefore let us consider first the part that heterophoria may play in binocular disharmony upon the ground. Furthermore, let us confine ourselves to this condition, ignoring at once all other visual states that are so wont to wriggle into the picture, such as squints of small degree, transient diplopias that are so often the precursors of insular sclerosis, and pareses and paralyses of the ocular muscles.

Symptomless and Symptom-producing Heterophoria

We cannot have discord where there is no rivalry. The processes of evolution have so shaped the visual pathway that only some check in the maze of development, or some unreasonable assault through the demands of modern life upon the binocular function, can create a symptom-producing situation. We may speak of heterophoria under two headings: (1) inherent (slight; marked); (2) acquired. Leaving out all questions of refractive and pathological states, the one great predisposing cause of inherent heterophoria is *dominant macular reception*. This may occur without rivalry, in which case symptoms as opposed to signs do not arise in later life; or it can be present in a slight degree (in this case with rivalry), thus creating a potential source of trouble, according to the visual destiny of the individual.

Heterophoria may be acquired at any stage in life from school age to the presbyopic period, either superimposed upon a dominant macular reception of slight degree or arising as a condition primarily induced by the circumstances of everyday life. To differentiate the one from the other is sometimes a matter of a little difficulty. In this the age of onset of symptoms helps. The man who has *acquired* heterophoria without the influence of an inherent condition tends to complain of ocular discomfort early in the process. So strong has been his binocular conception that he is awake to the first falter. There is another approach to the problem—namely, by an examination with the stereoscope of the binocular reception rate, and also the appreciation of depth. On the stereoscope such a case will demonstrate rapid alternation with those charts designed for the examination of simultaneous binocular perception, will readily appreciate simple depth, and will proceed to give a good account with the more exacting charts. All this is in direct opposition to the *acquired* heterophoria with an inherent foundation. It is a natural corollary (in these cases) that symptoms are proportionate to the primary strength of the binocular chain. Much that can be labelled heterophoria diagnostically is quite symptomless, and is the outcome of a strong inherent tendency.

* Read in opening a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Belfast, 1937.

In the innumerable occupations that shape the intricate design of modern life there are two things that prey for ever upon us. One is the call for prolonged concentration at close range, while the other is a natural worry with regard to the eventual outcome of our endeavours. Any cause that irritates the mind may easily hinder the smooth running of the former and add a new load to the latter. We are now treading the nightmare path of psychology, but not without reason.

The part that heterophoria may play in the induction and maintenance of a psychological state is not sufficiently emphasized. Too many times has the association been demonstrated for any doubt to remain. It is a matter of experience that the most intense headaches can be produced by heterophoria, headaches that act not only as a handicap at work but may actually confine the sufferer to his bed. If the ability to maintain an occupation depends upon detailed and accurate work, the carrying out of which in turn produces the ocular symptoms, the picture is then complete.

It is wrong to hold that all sufferers from heterophoria are constructed with the addition of a strong functional element in their mental architecture; but it is right to maintain that very many symptomatic cases are definitely unstable. A typical example of this is well shown in a female patient, aged 35, who for several years had confined herself to her house. Her condition bordered on panic. She requested that I should leave my consulting-room door ajar so that she could run from the house if she found the strain too great. She had three to four intense headaches every week. These began in the morning and worked up during the day. Her vision was:

Right ... $6/18 \frac{-0.5 \text{ Sph.}}{-0.75 \text{ Cyl.}} = 6/6$ 15°

Left ... ... $6/60 \frac{-1.25 \text{ Sph.}}{-1.25 \text{ Cyl.}} = 6/24$ 70° (partial amblyopia)

She was found to have 14 prisms of hyperphoria. With the addition of suitable prisms (she had had correction without prisms before) she improved greatly. Within a month she was walking in the country and was beginning to tolerate the presence of crowds and traffic. The dragging in her left eye was relieved. She was unsuitable for training.

The Symptom-producing Phorias

Of all the phorias that produce suffering hyperphoria easily holds the field. This is explainable on the grounds that the binocular vision is quickly strained above the horizontal plane. No doubt this constitutes a big factor in the production of miner's nystagmus. The Bishop Harman test demonstrates this very prettily. In vertical latent deviation there is little latitude, and subconscious control rapidly gives place to central conscious effort. Where these two meet there also lies the evil of their plotting. It may be remarked that certain of the hyperphorias are symptomless, which is perfectly true, for they are of the marked inherent type.

Exophoria with weakness of convergence constitutes the second group of symptom-producing cases. Here the occupation of the sufferer influences the picture. I would quote the case of a very busy solicitor who was about to leave his practice on account of his inability to give long hours to the close study of his cases, owing entirely to this condition.

Ocular rivalry cases are a further variety, while cyclophoria enters the field not so much as a primary condition but as an unpleasant addition usually to hyperphoria. It is present as a result of overaction of the torsion group of muscles, and its discovery is a warning not to show undue optimism with regard to prognosis.

Heterophoria in Relation to Flying

It is from this world of our civilization that we are asked to select our pilots of aircraft. Many of the potential causes of disharmony have been met with by the men in their studies and duties upon the ground. The ledger clerk, the draughtsman, the engineer, the man who follows an occupation calling for monocular estimation—all these have encountered the strain for varying periods. It is remarkable how rare it is to discover gross defects. It says much for the strength and the latitude of the binocular function.

The extent of the various deviations allowed for acceptance in the Royal Air Force is the result of long study, but cannot even yet be said to have reached finality. The subject is exceedingly involved. There is, for example, the problem of false panoramic conception, which has produced itself for solution and upon which work is now being done. In the past it was considered that the exophoric had a tendency to stall his aircraft, while the esophoric would come down heavily upon his wheels. But it is not by any means a simple process of fitting theory to facts. When the landing of an aircraft is affected by the presence of heterophoria in the pilot it is more usual for a general mixing of high and low approaches to take place. The explanation lies in the fact that an error in landing of one type results in an overaction by way of correction at another attempt, and as there is no stable point of reference the whole affair becomes erratic.

The cases of real interest are always those of pilots who have flown successfully and then suddenly experience difficulty with the final stages of their approach. An approach which errs within so small a degree as plus or minus five feet can end in a nasty accident, usually by the propeller catching the ground and turning the aircraft over. Repetition of these events calls for a very careful examination of the binocular state. Here it is wise to tread with caution. The disharmonies that heterophoria may produce in air-pilotage are well known and proved, but on these very grounds a false jump to conclusions must be carefully avoided. Every discovered phoria with a history of flying trouble is not for certain the absolute root cause. Mental and physical fatigue; the first indication of some illness of slow onset; a growing dislike to flying; neurasthenia—all these must be eliminated. It usually happens that the pilot with a pure ocular muscle defect is anxious to return to the full duties of his branch, and resents the visual handicap which is confining him to the ground. It may be asked, How does such a state come about in a healthy man on active service? The answer is that heterophoria may occur as a result of prolonged fatigue from concentrated flying, from tropical asthenia, from malaria, or from head injury. It is not by any means a condition that tends to persist once the primary cause, illness or accident, has cleared up, but there undoubtedly are times when heterophoria remains as a genuine state and requires active attention. It is usually found that such a condition is of the inherent type, which has been kept within bounds in a body physically and mentally sound, but that the constitutional upheaval has left its mark in a potentially weak spot. It is necessary always to form an opinion as to the optimum time to attack the condition by exercises. And it is easy

to be led astray. Let me quote two examples where I carried out quite useless treatment. The first was many years ago. The case was that of an officer with much flying experience. He passed through my hands in a purely routine manner. He had heterophoria of the exophoric type, far outside the permitted limits. He underwent a course of training, and admittedly showed much improvement, coming now well within the necessary standards. He had had, however, no particular trouble with his flying. On his return to aircraft he discovered that he had to face the situation from a new angle, and that flying was not nearly so simple. He was thankful when, in due course, he relapsed into his old state, in which he was perfectly happy. He was one of those cases of inherent heterophoria with dominant muscular reception, and it was I who from inexperience produced disharmony. There was another case, that of an officer with heterophoria of the esophoric type. From his history and from the clinical findings there was every reason to undertake training. This went well—in fact, too well. He began to develop gastritis. The clouds broke and revealed his mental landscape. He had acquired a growing distaste for flying. His faulty judgement of distance no doubt added fuel to this, but his training had again prepared him for the air. Therefore he transferred his discomfort lower down. I speak of these cases merely to emphasize the fact that we must always be prepared to stumble over them.

Treatment

It is not proposed to enter into any details, but rather to stress certain points that are wont to be omitted. In the first place, symptomless heterophoria is far better left alone. To obtain the ideal in binocular vision is a very worthy aim, but the sleeping dog is better left asleep.

In symptom-producing cases no time is wasted that is spent on a complete survey of the patient's mental framework. With regard to the order of attack our greatest lever is the stereoscopic sense. The more years one passes in the study of these cases the more one is inclined to relegate a special pathway to the realm of stereoscopic appreciation which, if intact, is ready always to answer to the call of stimulation. To reach it, and to use it to the best advantage, it is essential first to develop equal macular reception and then to work for a space upon simple stereoscopic pictures. I am now experimenting with a rotating stereogram made for me by Messrs. Theodore Hamblin. The idea here is to widen and strengthen the stereoscopic sense through those angles of the perimetric arc that are not specifically employed in this fashion. Usually after two weeks the road is open for the use of the amblyoscope, or one of its near relations.

I feel that the worst service we can do to this promising bud on the tree of ophthalmology is to fret round it with exaggerated care. Let us confine its nomenclature to reasonable proportions and tear aside the veil of mystery that is being drawn about it. To-day ophthalmic surgeons are divided into two groups upon the merits of orthoptic treatment—namely, those who consider it most valuable and those who do not. Both are right. The reason why this division exists is because too little time is given to analysis and too much to empirical treatment. The great variety of binocular disharmonies that are arranged under the group heading of heterophoria are very real conditions, carrying with them often extreme suffering. The relief that can be given by orthoptic treatment in a great number of these cases is too well established for argument.

The Use of Prisms

Prisms for dealing with symptom-producing heterophoria should be limited to two conditions:

1. As a means of helping cases that have occurred as the result of cerebral concussion. Sometimes an eye-shade is necessary as a temporary measure where there is troublesome diplopia. This temporary ocular occlusion can do no harm to the binocular receptive rate in adults. If the prognosis is favourable this does not last much over a month. Then a *full prism correction* is valuable, and may be demanded in both horizontal and vertical directions, at one and the same time. Reductions (in strength) are usually necessary in periods of two to three months. Then after the *safe interval*, which should be six months, possibly longer, training can commence. During the preliminary stages of training the prisms should be retained in balanced proportion to the progress of the case. Then training will take the upper hand, and the prisms can be safely discarded. Should, however, a residual and intractive hyperphoria remain, a safe rule is to prescribe such prisms as will relieve one-half to two-thirds of the uncorrected deviation. The remainder is nearly always mastered by the muscle tone which has been imparted through training.

2. As a means of relieving an inherent or acquired symptom-producing hyperphoria. Sometimes prisms, or indeed operations, may become the only means of affording relief. In other cases most valuable results may be achieved by a combination of training and prism correction. Once more reductions are made in prism strength during treatment. If a complete cure is effected so much the better, but candidly I think this ideal is rarely attained in the higher deviations. Then, again, it may be necessary to take up part of the strain by prisms. Never is it wise to give full balance in this manner, as some *active* vertical adjustment helps to maintain stability. It is most important to distribute the prism power suitably between the two eyes. It is not enough to divide this equally.

Always should the greatest care be exercised in selecting that which can be cured or markedly benefited from that which cannot.

O. Devold, F. Batt, K. Closs, and J. Backer (*Norsk Mag. Laegevidensk.*, July, 1937, p. 899) undertook in 1934 and 1935 a goitre survey of the inland district of Modum in Norway. They examined 4,560 of the 11,000 inhabitants. The measurements of the thyroid followed Hunziker's technique, and in many cases iodine determinations of urine collected over twenty-four hours were undertaken. The iodine content of the drinking water and of the milk and eggs was also estimated, and the findings were compared with iodine analyses of urine, drinking-water, milk, and eggs in Oslo. It was found that the iodine content of the urine and drinking-water was considerably lower in Modum than in Oslo. In 65.6 per cent. of all the persons examined some enlargement of the thyroid was found, the figures for the two sexes being 57.1 per cent. for men and 73 per cent. for women. The largest number of goitres were found in school children; in women it was most common between the ages of 20 and 29 in farming areas. Only 58 per cent. of the whole industrial population showed signs of goitre, as compared with 72 per cent. of the farming population. One reason for this might be that in the farming districts only 15 per cent. of the population ate fish at least once a week, whereas 63.5 per cent. in industrial areas ate fish once weekly or more often. Parous women suffered more often and from larger goitres than did nulliparae. The incidence of goitre increased with decrease in the social status of the inhabitants, and incomplete forms of cretinism were found. The authors conclude that prophylactic medication with iodine-containing sodium chloride would be more rapidly effective than a revolution in agricultural menus to include more sea fish and provide seaweed as cattle fodder and manure.

THE ACTION OF MEAT EXTRACTS AND RELATED SUBSTANCES AS GASTRIC STIMULANTS IN MAN

BY

WILLIAM ROBERT BOON, Ph.D., B.Sc.

(From the Department of Physiology, King's College, University of London)

Meat extracts cause a profuse secretion of gastric juice in animals, as was first shown in Pavlov's laboratory by Lobassoff (1897). He worked with dogs, equipped with a Pavlov pouch, and showed that the presence of Liebig's extract in the main stomach produced a marked secretion in the miniature stomach. Similar observations have since been made by numerous authors, all on Pavlov-pouch dogs or on comparable surgical preparations (Popielski, 1902; Gross, 1906; Lönnqvist, 1906; Orbeli, 1906; Kryszkowski, 1913; Zeliony and Sawitsch, 1911; Zeliony, 1913; Edkins and Tweedy, 1909; Ciminata, 1925 and 1926; Lim, Ivy, and McCarthy, 1925). But it does not appear to be accepted that similar effects are found in human beings. In many textbooks of physiology and nutrition statements such as the following are met with: "Commercial meat extracts are possibly of value as gastric stimulants."

Experimental Tests

A series of experiments on medical students has been carried out in order to establish this point. The technique of the fractional test meal introduced by Rehfuss (1914) was adopted. Bergeim, Rehfuss, and Hawk (1914) state that water is a strong gastric stimulant in humans, whereas Pavlov (1910) says that water was devoid of any stimulant action in his animal experiments. Apart from this no significant difference between the reaction of the human and the animal stomach has been recorded. It was not anticipated, therefore, that any marked difference in the reaction to meat extracts would be found.

The various test meals were given to the subject on different days and the responses compared. Ryle (1926) has shown that the gastric response of the individual to the same test meal on different days is essentially the same. This was confirmed in several subjects, and therefore any dissimilarity noted in the results from the substances examined is due to their varying stimulating power. The oatmeal gruel meal described by Ryle was used as the standard. The response to this is very constant for each subject. Using water as a standard is unsatisfactory, as the results vary greatly.

The following substances were examined. (1) Beef powder, prepared from dried lean beef. (2) Extracted beef: this is the residue of the meat after the water-soluble extracts have been removed in the manufacture of commercial meat extracts. (3) Direct extract: this is made by extracting meat completely with water and concentrating the resulting liquor. (4) The commercial meat extract known as bovril. (5) Sodium glutamate. This substance has a meaty taste and is used as a flavouring agent. It is not present in meat.

Technique

The tests were performed on a fasting stomach, in the morning before breakfast or in the afternoon after an early breakfast. If the stomach was found to contain more than a trace of food the test was postponed. After intubation the residual contents were removed and the stomach washed out with 200–300 c.cm. of warm water and the test meal administered. Samples were withdrawn as soon as the meal was finished, and subsequently at fifteen-minute intervals until the stomach was empty. In some tests warm water slightly less in volume than the usual bulk of the meal was given, and the substance under examination administered in a concentrated solution through the stomach tube. In this way any stimulation due to the taste of the extracts was avoided. There were no significant differences in the response obtained after administration of the extract in this manner and when the subject was allowed to taste the material.

The following determinations were made on each sample. The free hydrochloric acid and the total acid, and the pepsin, were estimated. In titrating the samples for the estimation of the free acid, *p*-dimethyl-amino-azobenzene, Töpfer's reagent (1894), mixed with half of its weight of methylene-blue, was used as the indicator. The mixed indicator exhibits a magenta colour on the acid side of the change point, a bright green colour on the alkaline side, and a neutral shade of pale grey at *p*H 2.9. The total acid was estimated by titrating to the change point of phenolphthalein. Pepsin was estimated by a modification of Mett's method. The tubes were prepared by the method of Christiansen (1912), and successive batches standardized before use against the preceding batch. 0.5 c.cm. of the unfiltered sample was mixed with 9.5 c.cm. of a phosphate buffer of *p*H 6.8 left overnight, and filtered to remove the mucus and protein matter as recommended by Ege (1924). The *p*H of the filtered material was adjusted to 1.2–1.3 by the addition of concentrated hydrochloric solution. The resulting solution was incubated with the Mett tubes at 35° C. for a varying period, depending on the strength of the pepsin solution. Weak solutions were left for several days. All calculations were based on the length digested in twenty-four hours. Four measurements were made on each sample. According to Patterson and Adler (1932) the pepsin is proportional to the cube of the length of fibrin digested. This measure was used in the present test. The results are shown in Tables I, II, and III.

Results

Table I contains the average HCl values as produced by the various substances. The figures indicate cubic centimetres of decinormal HCl. In Table II are given the

TABLE I.—*Table of Average HCl Values.*

TABLE II.—*Table of Emptying Times of Stomach*

	Average	Expressed as percentage of gruel
Gruel	97 minutes	100
Beef powder	107 ,,	123.6
Extracted beef	84 ,,	96.5
Direct extract	92 ,,	104
Bovril	63 ,,	74.2
Sodium glutamate	36 ,,	44.6

figures for the emptying times of the stomach. In the first column the average figures are shown, and in the second column the figures are expressed as percentages. The emptying time with gruel was called 100 per cent. in each separate experiment. For each individual the time taken for the stomach to empty with the different substances used was expressed as a percentage of that taken with gruel. The results were averaged, and, as will be seen, are not quite the same as the average times. In Table III the average pepsin values are given.

TABLE III.—*Table of Average Pepsin Values*

	Resting juice	15 min.	30 min.	45 min.	60 min.	75 min	90 min	105min.

Sodium glutamate ..	0.025	1.1	24.2	—	—	—	—	—

Beef powder, which represents whole meat, produces a marked secretion of HCl over a long period. The watery extract is not so powerful, producing a secretion not much greater than that of gruel. But the extracted beef is even less efficient. The most effective stimulant is bovril. Sodium glutamate leaves the stomach so quickly that its effect on HCl secretion is negligible. Beef powder delays the emptying time considerably as compared with gruel. Extracted beef and direct extract are not significantly different in their emptying times from that of gruel. Bovril shortens the time by one-third. Sodium glutamate makes the stomach empty very quickly. The extracted beef produced a very marked flow of mucus; in one case this was so great as to block the stomach tube.

The secretion of pepsin is high when beef powder is administered. Of the substances examined that was the only one which stimulated the gastric mucosa to secrete pepsin. The other substances do not differ greatly from one another in their effect on pepsin secretion, sodium glutamate being a possible exception.

Commentary

In conclusion it can be stated that meat extracts act as stimulants of the gastric mucosa. The gastric secretion so produced is normal in HCl content. Bovril produces a marked stimulation of the gastric mucosa with a stimulation of HCl which at sixty minutes after administration is nearly three times greater than that produced by gruel. It reduces the emptying time by approximately 30 per cent. as compared with gruel. Sodium glutamate causes such rapid emptying of the stomach that it is impossible to draw any definite conclusions as to its effect on gastric secretion.

These results have some clinical significance. Following acute illnesses there is commonly a depression of gastric secretion. The gastric juice is poor in HCl, but there is rarely any deficiency of pepsin. In such cases meat extracts, by stimulating the mucosa to an increased flow of HCl, restore the gastric juice to normal.

Conclusions

1. Meat extracts have a stimulant action on the gastric mucosa.

2. The water-soluble fraction of meat is almost as efficient in stimulating a flow of HCl as whole meat.

3. The secretion of HCl is greater with bovril than with any other substance examined, including whole meat.

4. Whole meat in the form of beef powder is the only substance examined which stimulated a flow of pepsin.

5. The emptying time of the stomach is less with meat extracts than with whole meat. Bovril reduces the time by 60 per cent. as compared with beef powder.

6. Sodium glutamate has little or no stimulant action. The stomach empties very rapidly when this substance is given.

I have pleasure in acknowledging the assistance of the medical students of King's College who were good enough to act as subjects. I am very grateful to Dr. O. G. Edholm, who has worked out the tables and has also prepared the paper for the press.

The annual report for 1936 of the Health Department of the municipality of Singapore records a continued heavy incidence of enteric fever. During the year 461 cases, including six of paratyphoid, were notified, compared with 424 in 1935. Of these cases, eighty-two were in school children. The notifications were more or less evenly spaced over the months, and there was no localized outbreak. The spread of infection is attributed to carriers among those engaged in preparing food sold by hawkers in the streets, and there is strong presumptive evidence that the hawking of ice-cream and iced drinks is often responsible. More arbitrary powers for dealing with food hawkers have recently been granted, but their full application will not be feasible until the passing of the new Food and Drugs Regulations. With regard to malaria, the report states that anti-mosquito work has been continued on a large scale. The chief undertaking during the year was the cleaning up of the breeding grounds of *A. sundaicus* in three river basins, following a sharp outbreak of malaria in the latter part of 1935. The greater part of the breeding grounds was dissipated by breaking down the containing bunds of numerous fish ponds, thus admitting tidal water. Those still out of reach of the tide were either filled in with debris from the demolished bunds or were connected together by deep drains, with a discharge to bigger drains protected by tidal flaps at their exits in the bunds. Nearly 200 fish ponds and over 500 vegetable ponds were treated by these methods.

TREATMENT OF SPASTIC PARALYSIS

BY

F. H. MILLS, M.B., B.S.

(Formerly Tutor in Medicine, St. Andrew's College, University of Sydney)

The system I propose to outline was developed more than twenty years ago, during the war in the course of work done on soldiers convalescent from cerebrospinal meningitis. It was developed quite empirically, and the theoretical principles underlying the method have only recently been applied. Since the war only the more severe spastic cases—for example, those suffering from cerebral diplegia or Little's disease—have been treated. Recently, however, the work has extended to less spastic cases, such as post-thrombotic paralyses.

Aetiology

The causes of spastic paralysis are many. They include birth injury; encephalitis following the acute specific fevers, such as diphtheria, typhoid, or poliomyelitis; syphilis; and infantile cerebral haemorrhage. Arrest of growth or failure of development of the cerebral cortex is responsible for most cases. There are, too, other obscure causes. In any event the result is damage to the cerebral cortex of a greater or less degree, and this is manifested by motor, sensory, and psychic disturbances. Many of the patients seem to be idiots. Over 50 per cent. of our series of 200 cases gave this impression because of dribbling of saliva and inability to control the facial muscles and to express themselves, but after treatment only four have had to be rejected as true idiots (c.f. case reports). Many patients who were apparent idiots showed quite normal intelligence after the spastic condition had been cured.

Sensory Effects

In spastic paralysis the extent of the associated sensory disturbance is not generally realized. It manifests itself, however, in various ways. There is loss of appreciation of the relative intensity of different stimuli—for example, fine differences of heat and cold and touch are imperceptible. Appreciation of spatial relationships may be lost, the patient being unable to identify the precise part stimulated (tactile localization) or to discriminate between two points of stimulation (tactile discrimination). Some interference with the interpretation of proprioceptive impulses, especially in the smaller joints, may be noted. The muscle spasm itself upsets the normal proprioceptive impulses from both muscles and joints. Astereognosis may also be present.

The importance of these sensory disturbances must always be borne in mind. All the phenomena of incoordination are for the most part of sensory origin. It follows that educative therapy must also have a sensory basis. The brain must literally be flooded with a sequence of properly regulated sensory impulses.

Motor Disturbances

There is seldom any loss of the impulse to make a movement, but the muscle spasm and sensory impairment cause gross clumsiness.

The increase in tone may be localized to one group of muscles, but is more usually general. Normal tendon reflexes are exaggerated, and the Babinski and Oppenheimer reflexes and Gordon's reflex and ankle clonus may develop. Receptive areas, stimulation of which gives rise to spasm of the spastic muscles, are situated at the distal parts of the extremities. Any stimulation of these areas in the course of routine treatment must be avoided.

The muscles of the spinal or decerebrate animal, and usually all spastic muscles, respond to a stretch with an increase in tone. This so-called stretch reflex, due to the presence of stretch receptors in the muscle and lying parallel with the muscle fibres, is especially marked in the physiological extensor group of muscles. Because of this reflex response any attempt to move a joint when the muscle tonus is still increased results necessarily in a further increase in the muscle spasm. This must be avoided; the muscle groups should first be inhibited (*vide infra*) before any movements involving stretching are undertaken.

Ataxia in this condition is due to both sensory and motor involvement; it is often marked and of a cerebellar type. There is also decomposition of movement, any action being carried out as if by numbers; thus in trying to bring the heel on to the opposite knee while lying in bed the heel is dragged along until it reaches the knee, raised to the proper height, adducted, and finally placed on the knee. Asynergia is due to the lack of co-ordination between antagonists and agonists. If the patient attempts to flex the elbow the triceps which antagonizes the movement may go into tonic contraction. Dysmetria is shown in that the force employed in any action is ill adapted to the aim of the movement; the hand usually shoots past an object which is to be picked up. Occasionally the spastic paralysis may be associated with some flaccid paralysis, usually of the neck muscles (Fulton, *Arch. Neurol. Psychiat.*, 1934, **31**, 211).

Treatment resolves itself into inhibition of the motor spasm, and intensive sensory, and to a less extent motor, education. The motor education must follow the sensory. The patient may be likened to a baby. There is as yet no appreciable sensory development of the cortex, and so a sensory education together with the inhibition of spasm must precede motor re-education. The simplest actions are taught first and accessory movements added until the finer and more complex muscular efforts are mastered. All the harmful phenomena of the disease are progressive. The exaggerated muscle tone increases, leading finally to contractures and deformities of joints. Sensation becomes more and more impaired, and psychological changes follow in a vicious circle. Thus it is of extreme importance that the patient should begin treatment early.

General Treatment

The general health is supervised and adequate food and rest provided. The patients are told to rest from 2 p.m. to 4 p.m. and to get plenty of sleep at night. If of school age they do not attend school, but are given lessons at home by the mother or else take a correspondence course. School is forbidden because the spasticity is likely to increase in front of others: the awkwardness of their movements often excites jeers from other school mates; they become nervous, their awkwardness increases, and they suffer psychologically. A further point is that the children are often backward and do not get the same benefit from teaching as the normal members of the class. They progress better with individual tuition. The time taken for treatment in the clinics varies from half an hour to an hour each day, depending on the severity of the case.

It should be noted at this point that we do not advise certain forms of therapy for the following reasons: electrotherapy, since it causes muscular contraction and

heightened tone; massage, because it increases the tone of spastic muscles, especially if applied to the receptive areas; and also passive and active movements of the joints of the extremities, for by stimulating the stretch reflex they too cause heightened tone of the muscles. Splinting and bracing is also avoided as much as possible. It is harmful in the extensor group of muscles and the more distal muscle groups, but at times may be used advantageously in inhibiting spasm of a proximal group of muscles, usually flexors—for example, the hamstrings. In these proximal flexor groups the lengthening reaction is elicited and is not harmful. Hydrotherapy is valuable, but the cold douche must be avoided, since it increases tone.

Inhibition of Muscular Spasm

The first essential of treatment is to inhibit the muscular spasm. A warm bath at a temperature of 37° C. is given at the start of treatment. This is a necessary preliminary in any form of education of spastic muscles, and it produces marked relaxation of the spastic muscles. The patient is asked to relax and breathe deeply. At the same time the affected muscles are gently manipulated. This stimulus is a powerful inhibitor of muscle tone. It is important to remember that the most proximal muscle groups of a limb which is in spasm (the deltoid and pectoralis major muscles, etc., in the upper extremity) must be inhibited first; thus the receptive fields are avoided. The muscle groups are treated proximo-distally in succession until they relax, the manipulation being as gentle as possible, especially when the distal receptive fields are approached.

These gentle stimuli cause a state of inhibition of the spasm and what is called the inhibitory after-period develops. This period is gradually extended as treatment proceeds, and generally becomes permanent—that is, conditioned. During this inhibitory phase the muscles may be stretched without evoking the stretch reflexes. The attendant then passively moves the joints, starting very gently with the most proximal joint. At the first sign of return of tone the muscle is again inhibited and the joint again put through a complete range of movement. These movements must be very slow and the patient's attention should be concentrated on them, the attendant saying, "I am abducting the shoulder," or, "I am adducting the shoulder." By this "attention training" the proprioceptive sensations are reinforced and sensory re-education takes place. "The patient's mind must be made to follow the movements of the joints and be educated by these movements. . . . The extremities educate the brain." New nerve pathways are opened up and proprioceptive sensation will slowly return. It is essential, however, that with each passive movement the attendant secures the absolute mental co-operation of the patient.

This routine is slow. Advanced cases may need many weeks of inhibition of the more proximal muscles before the distal groups can be treated and the smaller joints moved without exciting the stretch reflex response. However, in time this can be done, and then sensory education of the more distal joints may be undertaken. Until sensory education is complete nothing but the simplest active movements are permitted. The patient and the parents are taught these principles, and may apply them at all times at home, fatigue only being avoided.

As in Pavlov's experiments, we find that inhibition will readily spread. In patients with dribbling of saliva and incontinence of urine and faeces, if the muscles of the face and neck are inhibited and dribbling ceases it is found that often the bladder and rectum will also be controlled. It is always easier to inhibit successive groups of muscles. Speech returns to some degree without any special training. With continued inhibition and sensory training the muscles develop a state of conditioned inhibition and the spasm disappears. This training may take many years, but during the whole of this time special movements are taught. The first acts taught are those essential to washing, feeding, and dressing. Later on the finer movements such as writing and playing the piano may be acquired.

Special Exercises

Quite apart from the ordinary relaxation exercises, in which the patient is asked to relax or to take a deep breath and relax, deep breathing and sighing exercises are helpful. In another exercise the muscles of the limb are loosely hunched up and released, starting at the shoulder girdle and proceeding down to the fingers. If when the fingers are being moved the muscles of the forearm become spastic the patient is told to relax and the dorsum of the hand is percussed lightly with the attendant's fingers.

The lack of balance, very noticeable in this condition, is to some degree overcome if the attendant can induce the patient to recognize contact between the sole of the foot and the substance of the ground or floor. For this reason in all walking exercises coir matting is used, so that the proprioceptive stimuli will be reinforced by increased cutaneous impulses. Stability is obtained by teaching the patients to climb steps. The weight of the body is forced on to each foot alternately with the patients concentrating all their attention on each movement. Long perseverance in this step-climbing will eventually result in the linking up of the physical balance and mental control. Specially constructed steps covered with coir matting allow the attendant to supervise every movement and give the patient greater confidence. A sand trough is used later, and the greater effort required to keep the balance in the sand further reinforces the sensory impulses and slowly greater control is developed. It is essential to train the patient to get the heel down on the ground, and this is done by the attendant holding each heel. The patient is taught also to stand firmly on both feet and to bend and straighten the legs. The individual control of movements of both the ball and heel of the foot must be taught, and such teaching is accelerated by these methods of proprioceptive reinforcement.

Exercises in Co-ordination

The patient, lying down, is asked to place the heel of one foot on the opposite knee, guided by the assistant if necessary. The movement must be slow and purposive, but the patient must remain relaxed. The child is directed to place his foot in the assistant's hand, which is moved to and from various positions until practically every muscle in the lower extremity has been brought into play. Similar controlled movements are practised with the upper limb. No rhythmic movements or quick cyclic movements are ever attempted.

Often a patient has the appearance of idiocy because the muscles which control the action of swallowing are spastic. Saliva continually dribbles from the mouth, and speech is defective or absent. Early education of these muscles is imperative. Inhibition of spasm is effected, and a fluid pleasant to the palate of the patient must be given at regular intervals in very small doses; sweetened fruit drinks are particularly useful. An effort is made to swallow. Every case has responded to this method. Incontinence of urine and faeces tend to clear up at the same time, due to the spread of conditioned inhibition.

The muscles controlling the movements of the tongue must also be subjected to special exercises. The patient is trained to protrude the tongue, and also to curve it upwards towards the nose and downwards towards the chin. The movement towards the nose is the hardest to perform. All the sounds in which the letters "t," "d," "n," and "w" are involved are the most difficult to utter, and should be concentrated upon. The patient is also asked to point the tongue to either side of the mouth. The child is not asked to put all his mental effort into the movement but is encouraged to relax: the movements are assisted by the attendant, and are attempted only after relaxation of muscle tone has been attained.

A spasm of the muscles of the neck sometimes interferes with the mobility of the lower jaw. It may be noticed that upon waking speech is quite good before full consciousness is established, but immediately consciousness is restored the power of speech is lost. To combat this it is necessary to bring the overcharged muscles to a normal degree of tonicity by tongue exercises. Facilitation is assisted by the continued slow repetition of verses of poetry.

In the finer movements of the small joints of the hand there is often some loss of power. After relaxation of the proximal muscles has been obtained the patient is encouraged to concentrate on mastering these finer movements. When the child first starts to write his hand should be guided by the attendant. Exercises in which the child has become proficient are not repeated each day; attention is centred on the actions he cannot perform. At intervals of two weeks, however, the full routine of exercises is carried through.

Long hours of sleep are necessary, and the child should never be disturbed from his rest, because during sleep there is inhibition of the spasm. This is in accord with Pavlov's theory of sleep. Sometimes there is sleeplessness due to painful spasm. The child may make while sleeping an involuntary movement, which becomes immediately a painful spasm which awakens him. The parents must be trained gently to manipulate such spasms, so that the patient sinks back into a quiet sleep.

Treatment of Fixed Deformities

Most fixed deformities will yield to stretching by special apparatus. Inhibition of spasm must be effected first, and the time of stretching must not exceed half an hour each day and should never cause pain. Some few cases of fixed deformity may need tenotomy (only three in our series of 370 patients). No patient under treatment has ever developed deformity. It is therefore essential to place patients under treatment early. The first manifestations of disease occur at 8 months of age, and the first sign is difficulty in abducting the legs. Treatment should be begun at this early age if possible.

Special surgical boots may have to be worn to combat inversion and eversion deformities of the feet. The toe-caps of the boots are removed to allow free movement of the smaller joints, and to stop spasm consequent on compression of the distal receptive areas. Only the heel of the boot should be fully built up, otherwise there will be some interference with the freedom of toe movement.

Other Forms of Treatment

Ramisectomy has now no part in the treatment of spastic paralysis. There is no sympathetic nervous supply to skeletal muscle other than that to the blood vessels in the muscles (Hinsey, *Physiol. Rev.*, 1934, **14**, 562). In our experience ramisectomy is often harmful, the preliminary flaccidity of the muscles lasting only for a short period. Later the muscles regain their spasticity, and by this time the general condition has often deteriorated. Retention or other disturbances of micturition may follow.

Stoffel's operation of partial section of the motor nerves to a group of muscles, which has been applied especially to the obturator nerve, results at first in a dramatic reduction in muscle tone. Later on, however, the paralysed part of the muscle becomes fibrosed and retracts, spasticity returns, and the proprioceptive muscle sensation is grossly altered. The muscles are even more incoordinate and spastic than before.

The usual re-education by massage and remedial exercises seems to us inadequate. It is only the extreme attention to detail and incessant application that leads to results such as have been obtained in the Kenny clinics. The ideals of treatment of each form of educational therapy are the same—that is, relaxation of the spasm and co-ordinative exercises—but it is in the fulfilling of this desire and in the strict application of detail that the usual routine breaks down. Several clinics, notably in America and England, are striving after the ideal, but they do not go quite far enough and their methods are not sufficiently intensive. For example, one method advocates the training of co-ordination by swimming exercises in a warm pool. The warmth inhibits the spasm, and the water takes the weight off the limb and the stretch reflex is not evoked so easily. This is quite true, but the swimming is an active form of motor education. The effort of movement causes an increase in the central excitatory state and the muscles regain their hypertonicity. Education of the spastic child must start at the simplest actions and gradually progress, just as does a baby. Rhythmic exercises and cycling exercises also start at too advanced a stage, and so defeat their object. A spastic patient may be taught in a short time to ride a bicycle and yet be totally incoordinate in using the lower limbs. Of course a degree of progress is made and good work is being done in these few interested clinics, but elsewhere these patients are often looked upon as hopeless cases.

Illustrative Case Reports

Case 1.—A child, aged 8, of Townsville, Queensland, had had spastic paralysis from birth; labour was prolonged, and the infant very cyanosed. Had orthodox remedial therapy treatment from the age of 1 until the age of 8. On examination in March, 1933, he could not stand up alone, walked on the toes with his feet wide apart, and continuously fell. He was unable to get up after falling. There was incontinence of urine and faeces, and saliva dribbled from the mouth. His speech was explosive, and he could not feed, wash, nor dress himself. He appeared to be subnormal mentally. Contractions of the tendo Achilles and muscles of shoulder girdle were noted, and there was flaccidity of wrists and hands.

By November, 1934, the child was almost normal. He could walk normally, even when blindfolded. Incontinence of urine and faeces was no longer present, and there was no dribbling saliva. He could wash, dress, and clothe himself, and could use a pencil in writing and speak normally.

Case 2.—A youth, aged 18, of Townsville, Queensland, was spastic from birth. On examination in July, 1935, both arms and legs were found to be affected. He could walk, but only with the typical difficult scissors gait. When he sat on a chair there was a spasm of the hamstring muscles, the lower legs would coil underneath the seat, and he would fall forward on his face. He could feed and dress himself only with great difficulty, and saliva dribbled from his mouth.

On re-examination in January, 1937, after eighteen months' treatment, he could walk normally and control his facial

muscles. He could do general work and even fine work with his hands. He now earns his livelihood assembling wireless sets.

Case 3.—A girl, aged 7, of Sydney, New South Wales, whose spasticity was noticed at the age of 4 months, was flaccid until a movement was attempted, and then there was a tremendous explosion of incoordinate muscular energy. Her hands would be retracted to the back of her neck. Oculogyral spasm was present, dribbling of saliva, and incontinence of urine and faeces. She was thought mentally subnormal, but had treatment from the age of 4 months up to 7 years, when she was given up and regarded as hopeless. She was then treated privately for the following three years, during which time she learnt to read and write, and to sing and play the piano, and could walk with the aid of a stick. Treatment then ceased for ten years. Has had six months' further treatment in 1936, subsequent to the opening of a clinic in Brisbane, and can now walk without the use of a stick.

Case 4.—A child, aged 4, of Brisbane, had paralysis of a mixed flaccid and spastic type from birth. There was marked spasticity of the legs, but flaccidity of neck and arms. This patient was unable to lift his head from his chest, had incontinence of urine and dribbling of saliva, and could not speak. Though pronounced an idiot, he was admitted to the Brisbane clinic in June, 1935.

On re-examination in January, 1937, he could hold his head up normally, and was beginning to speak and feed himself. Fixed contractions of the hamstrings were being reduced gradually. The incontinence of urine and dribbling of saliva had stopped, and intelligence was quite good. Treatment has been continued.

Case 5.—A patient from Townsville had marked astereognosis associated with spasticity. In 1934 the patient had sustained severe head injury, for which decompression was performed. A flaccid paralysis of the right leg cleared up, leaving spastic paralysis of the right face and arm associated with extreme astereognosis. He could not discriminate between a golf ball and a small nut placed in the hand. He had standard remedial therapy for one year without any improvement, but recovered completely after clinic treatment for twelve months.

Case 6.—A child, aged 18 months, had been spastic from birth; the prognosis was regarded as hopeless, and spastic contractions of the arms and legs were already developing in spite of treatment. Dribbling of saliva was present. Babinski responses were present with ankle clonus on both sides. Treatment for twelve months resulted in marked improvement. The reflexes are now normal, there is no dribbling of saliva, and the patient is much brighter mentally. We believe that this child will be normal by the age of 7.

Results of Treatment

The patients we have dealt with on the lines indicated above have been the very worst spastic cases. Even the very worst patients, who on examination appeared to be idiots with marked spastic contractures, have sometimes proved to be of quite normal intelligence and capable of the finest co-ordinative movements such as those involved in dancing and piano playing. Two hundred cases have been treated. Many of them are the rejects from all over the world, and at the beginning of the work only those cases that were pronounced hopeless by a medical committee were treated. No published results we know of can compare with those achieved in Australia.

The treatment requires, above all, energy, enthusiasm, and the maintenance of a cheerful outlook. These factors are best achieved where trained persons are working together, competition and similarity of ideas sustaining the mutual interest. It is found in the clinics that two years' training in both flaccid and spastic types of paralysis is essential before real proficiency is attained. At the end of this time the trainees are examined, and if successful are granted the clinic diploma.

The notes on special exercises have been taken from Elizabeth Kenny's *Infantile Paralysis and Cerebral Diplega* (1937, Sydney).

Clinical Memoranda

Ileo-caecal Volvulus in a Mental Patient

It is well known that anomalies in the later stages of intestinal development give rise to conditions in the right side of the abdomen which may lead in later life to a variety of morbid consequences (Waugh, 1920). According to Dott (1923), normal fixation and downward elongation of the ascending colon occurs during the third stage of rotation of the gut, at or about the twelfth week of intra-uterine life. In a proportion of cases, however, deficient fixation and excessive downward elongation of the caecum and ascending colon takes place at this stage of development, giving rise to a mobile colon so that the caecum may occupy one of many abnormal situations. The case reported is an instance of acute obstruction developing as the result of an unduly mobile caecum (Marnoch, 1913–14).

CASE RECORD

The patient was a single woman, aged 40, of poor physique and nutrition, and with a history of pulmonary tuberculosis since adolescence, who was admitted to the Murray Royal Mental Hospital on April 19, 1936, in a state of acute agitated depression.

In December, 1936, as a result of refusal of food, she began to lose weight rapidly, and had to be tube-fed twice daily. On January 21, 1937, during the epidemic, she developed influenza, with a subsequent lighting up of the old tuberculous pulmonary lesion, and from then until the date of her death she ran a remittent pyrexia. During this period she became markedly emaciated.

At 6.30 a.m. on February 16, on returning to bed from stool, she complained of severe pain in the lower abdomen. On examination the abdomen was tender and tense, and there was a large tympanitic swelling occupying the right iliac fossa and hypogastrium, and extending almost to the umbilicus. The patient was restless and obviously in great pain. She collapsed and died at 11.55 a.m. Although a tentative diagnosis of acute intestinal obstruction was made, it was considered that operative intervention was not justified on account of the patient's extreme weakness and acute phthisis.

Post-mortem Findings.—On opening the abdomen the grossly distended caecum, dark purple in colour but still lustrous, filled the lower right portion and extended well over to the left side. The volvulus was reduced with great difficulty, and it was then found that the lowest four feet of ileum had passed anterior to the displaced caecum and become incarcerated in the pelvis. This portion of small intestine was, like the caecum, intensely congested and gangrenous. The mesentery of the lower ileum was continued on to the caecum and ascending colon. There were several old tuberculous scars in the lower ileum, one of which, one inch proximal to the affected bowel, formed an annular cicatrix which considerably narrowed the lumen. The large intestine distal to the volvulus was collapsed, and there was a notable absence of intra-abdominal fat. Both lungs were extensively affected by tuberculosis, but the other viscera showed no evidence of disease.

It is probable that the events leading to the condi occurred in the following sequence. Mobilization

intestine in this case was no doubt exaggerated by the somewhat rapid absorption of fat from starvation and phthisis. When the patient got out of bed the whole ascending colon probably sagged, until, together with the caecum, it assumed the shape of the letter J. It is then easy to imagine how a loaded or distended ileum might be forced down into the pelvis by the effort of straining at stool. By reason of the attachment of the abnormal mesentery, the downward displacement could take place only anterior to the caecum, and thus produce a volvulus.

We wish to thank Dr. W. D. Chambers, physician-superintendent, Murray Royal, Perth, for his kind permission to publish this case.

An Unusual Cause of Volkmann's Ischaemic Contracture

A boy, aged 8, while playing fell on a nail, which penetrated the volar aspect of the right forearm just below its middle; a dressing was applied at his home, but on the fourth day the temperature rose and pus exuded from the puncture. He was taken to the surgical out-patient department, where anti-tetanus serum was given and the wound cleaned. He attended for dressings regularly for fourteen days, by which time the wound had closed. It was observed, however, that he was developing a contracture of the fingers; consequently he was transferred to the section for orthopaedics.

Showing extension of fingers on flexion of wrist; also scar of puncture.

Condition on Examination

There was no evidence of wasting in the forearm. A small closed bluish spot with a slight halo around it was seen on the ventral aspect of the forearm. This spot, with about one inch of skin around it, was attached to the underlying deep fascia. The muscles in the middle third of the forearm around the wound were found to be indurated. Sensations were not diminished, and pronation and supination were not affected. The hand showed a typical deformity of Volkmann's ischaemic contracture. On attempting to extend the wrist the metacarpo-phalangeal joints became dorsiflexed, whilst the interphalangeal joints became flexed and resisted forcible extension.

The patient was admitted to the wards, and after attempts at manual correction it was found advisable to intevene surgically, and the operation of stripping the flexor muscles from the internal epicondyle of the humerus was performed. The incision was extended further downwards to the site of the scar.

Operation

Macroscopically the muscles at their origin looked healthy; lower down in the middle third the deep fascia was fibrosed and hard, a specimen of this being removed. The muscles underneath looked brown and oedematous, and a piece was taken. The hard epitrochlear gland found in the upper part of incision was also removed, and all three specimens were sent for miscroscopy. The fingers were then stretched and were individually placed on finger-splints. The whole hand was now hyperextended and placed on a cock-up splint. The wound healed by first intention. After regular massage and stretching the patient was discharged one month later and attended as an out-patient. The splints were removed a month later, the hand having regained its normal movements. He was seen regularly once a week for three months, when he was discharged as cured.

The specimens taken were examined by our chief pathologist, Dr. H. Barsouma, who reported:

"1. *Deep Fascia.*—This is thickened, as also are its blood vessels. There is a fair amount of round-cell infiltration (plasma cells and lymphocytes), especially perivascular in distribution.

"2. *Muscle.*—There is a definite increase in the fibrous tissue between the muscle bundles, with a slight amount of small round-cell infiltration. The muscle fibres themselves show a certain degree of hyaline change.

"3. *Lymph Gland.*—This reveals marked fibrosis, especially in the central part; the periphery shows the lymph follicles with their germ centres practically unaffected."

Conclusion

Volkmann's ischaemic contracture is nearly always due to a fracture round about the elbow-joint, the determining factor being obstruction of the venous return due to either extrinsic or intrinsic causes—extrinsic such as tight bandaging, and intrinsic such as pressure by blood clot. Brooks and Jepson's work shows the intrinsic cause due to a combination of events: venous obstruction, serum exudation, and swelling of soft structures pressing on vessels and nerves. The unusual origin of the case is a subject for discussion. Brooks and Jepson's theory can be explained in such a case. The sepsis which had set in, the outlet being small, had produced swelling and induration of the soft parts, causing pressure on vessels and nerves, and venous obstruction. Sir Robert Jones, however, has declared that ischaemic contracture is due to acute venous obstruction and does not occur where the obstruction is gradual. Here also the original puncture might have injured the vein and produced clotting, which extended to the main vein, causing acute venous obstruction.

The interest of this case presents itself not only in the most unusual cause but also from the medico-legal point, for it shows that ischaemic contracture may take place in a forearm irrespective of fracture or compression by bandage or splint.

Alexandria. Orthopaedic Surgeon, Government Hospital.

Reviews

INTERRELATION OF DIGESTION AND HEALTH

Digestion and Health. By Walter B. Cannon. (Pp. 160; 14 figures. 6s. net.) London: Martin Secker and Warburg. 1937.

Professor W. B. Cannon, who has contributed greatly to the better understanding of the physiology of digestion, has had the happy idea of rewriting in popular form the lectures which he gave at the centenary celebrations of Beaumont's classical work, and publishing them in an interesting book on the interrelation of digestion and health. William Beaumont, a Connecticut Yankee serving as a United States Army surgeon, persuaded a former patient to come and serve him. This man had had a severe gunshot wound of the left upper abdomen, resulting in a gastric fistula. During the years of their relationship as master and man, physician and patient, Beaumont made a series of observations on the gastric secretion of his patient under varying conditions of health and illness, temperance and intemperance, placidity and anger, which laid the foundation of a sound knowledge of stomach digestion. Since his student days Professor Cannon has been interested in, and prosecuted researches into, the physiology of digestion, and has particularly contributed to the application of *x* rays to the understanding of digestive problems. His Beaumont Lectures on "Some Modern Extensions of Beaumont's Studies on Alexis St. Martin" contained an account of these and related researches, and are now submitted in a more popular form in the book under review.

Beaumont's early observations showed that the sight or smell of appetizing food not only caused the mouth to water but brought about a flow of gastric juice as well. Hunger is associated in our minds with an ache or gnawing pain referred to the lower chest region. It is not a general sensation; it does not even increase progressively if one goes without food; hunger strikers cease to feel hungry after a few days. It is a pang which has been shown to synchronize with contractions of the stomach. These contractions, more or less rhythmical, are influenced in various ways. They are stilled by taking of food. Sleep does not check them; indeed, they may interfere with sleep and produce restlessness. Chewing movements will stop hunger pangs. Not only swallowing, but great emotional excitement arrests the digestive functions, checking the muscle grippings associated with hunger. Smoking weakens and may completely stop them; strong alcoholic beverages have the same effect. Vigorous exercise inhibits them, probably by contraction of the abdominal wall such as follows tightening the belt. Why the stomach when empty contracts with so much greater power than when engaged in digesting a meal is probably associated with the blood content of glucose; the injection of insulin, which is succeeded by a fall of blood sugar, is a valuable stimulus to hunger in patients who are enfeebled or ill. Thirst appears to be a different phenomenon, though it can be even more insistent, more intense than hunger, and lead more rapidly to distress and death. The feature of thirst which practically all observers agree upon is the unpleasant sensation of dryness in the mouth and throat. Cannon's theory is that when the water supply of the body begins to run low from dry external conditions, excessive sweating, profuse diarrhoea, the salivary glands, because they require water to produce saliva, are particularly affected. If they fail to pour out their product in sufficient amount the back of the mouth becomes dry and sticky, and thirst is experienced. The theory is substantiated by experiments showing that all methods used to lessen the water content of the body—sweating, haemorrhage, and avoidance of drinking—were accompanied by a reduced output of saliva.

Digestion is of course essential for the maintenance of bodily vigour. Ordinarily we are only vaguely aware of the processes of digestion occurring inside us. When well supported and permitted to have their own way the stomach and intestines do their work well. Most of their difficulties come from the outside. Stress or emotion may bring about an abolition of movements in stomach and intestines. Cannon relates this to the extrusion of adrenaline into the general circulation as a result of pain, fear, and preparation for fight or flight which he has previously drawn attention to, since adrenaline, by stimulating the sympathetic nerve endings, brings about an inhibition of movement in stomach, intestine, and colon. He quotes a patient of Alvarez who continued ill for a week with much disturbance of digestion and only recovered when the doctor learned that she was worried about a bill and, as a therapeutic measure, paid the bill. This is the only sentence that could be taken exception to in recommending this admirable book to the general public for perusal.

PHARYNGEAL DISEASES

Les Maladies du Pharynx. Clinique et Thérapeutique. By G. Canuyt. Avec la collaboration de MM. Reverchon and Truffert, et le concours de Ch. Wild. (Pp. 790; 216 figures. Broché, 180 fr., cartonné toile, 200 fr.) Paris: Masson et Cie. 1936.

The pharynx might appear a somewhat restricted region to be made the subject of an immense volume of nearly eight hundred pages, but Professor Canuyt has undertaken this great task with the collaboration of the late Professor Reverchon of Lille, Dr. Truffert of Paris, and Dr. Ch. Wild, his own pupil at Strasbourg. They have had other assistance in special chapters. Professor Gery writes fully on the histopathology of tumours, Dr. Gunsett on treatment by radiation, and several others contribute sections on the relation of diseases of the pharynx to general medicine. It need scarcely be said that in a work so immense the subject is approached from the broadest standpoint, and special sections are devoted to the teeth, and especially to disorders connected with and arising from the wisdom teeth. There is even a section full of interest and good sense on forensic medicine as it concerns the specialist; this appears to indicate an increasing disharmony between Medicine and the Law in France, and it is presumably therefore all the more necessary to call attention to risks and liabilities whereby harsh penalties may be incurred.

The inflammatory diseases af the pharynx, nasopharynx, and tonsils are naturally described in great detail. It is interesting that there is a strong inclination to the view that Vincent's angina does not exist as a pathological entity, but is an epiphenomenon which masks some other pathological condition. Paul Chevalier is quoted to the effect that there is always some underlying malady. This may perhaps be going too far, but it emphatically calls attention to something which is not always understood in the nature of Vincent's angina. Dr. Truffert is anxious to suppress the term Ludwig's angina because it is not an angina and because Gensoul described the condition completely in the *Journal Clinique des Hôpitaux de Lyon* six or seven years before Ludwig. "Phlegmon septique du

plancher de la bouche de Gensoul" is the nomenclature adopted in this book.

The histopathology of malignant disease receives an elaborate general description, and tumours are described separately under the three rubrics of the tonsil, the nasopharynx, and the laryngopharynx. The various methods of treatment are described in detail, both surgical and physical, but there is a reluctance to quote any evidence on the results obtained. However bad these may be they should be frankly given so that some estimate, however imperfect, may be formed of their value. There is an inclination to resort to simple excision in all operable cases, but the section on the surgery of the laryngopharynx is unexpectedly found to be disappointing.

The authors say that they have tried to avoid "redites," and some repetition in a book so designed is inevitable, but there is much that might have been eliminated without spoiling the form of a magnificent collection of essays. Although the book is rather larger than it need have been, Professor Canuyt and his friends have made a splendid and permanent contribution to French medical literature, and in particular it forms a lasting memorial to Professor Reverchon.

BUCHANAN'S ANATOMY

Buchanan's Manual of Anatomy, Including Embryology. Edited by J. E. Frazer, D.Sc., F.R.C.S. Sixth edition. (Pp. 1,772; 1,042 figures. 35s.) London: Baillière, Tindall and Cox. 1937.

The sixth edition of *Buchanan's Anatomy*, the last issue of which was edited by Professors Wright, Parsons, Frazer, and Barclay-Smith, has now appeared under the sole editorship of Professor J. E. Frazer. The present issue of this work retains much of the original character which has gained for it a well-merited and firmly established place among British textbooks of anatomy. Previous editors have contributed their particular characteristics to the whole, which contains a fund of information not included in any book of the same category, and which is the outcome of many original observations and work of the writers themselves. Professor Frazer's special contribution is the section on embryology, including general embryology and the development of special organs. His treatment of this subject is unique, and he has amply illustrated it by diagrams and rough sketches founded on microscopical sections and his own models of human embryos which aid in effectively explaining the text.

The terminology used in this edition is the revised nomenclature, which has been adopted by the Anatomical Society of Great Britain and Ireland, with the addition of certain of the older historical names which are still in common use. These are usually mentioned once, when the subject is introduced, or recorded in the glossary. The book as a whole may be regarded as conservative in type, and one which is much needed by students of the present time when the traditional methods of the older surgical anatomists are apt to be set aside in order to make room for the introduction of more recently acquired knowledge on special subjects which is perhaps better dealt with in monographs on the particular organs and systems concerned. There are some, however, who would like to see a closer association of microscopical with macroscopical anatomy than is customary and the introduction of good illustrations representing the structure of important organs such as the mammary or lymphatic glands into the textbooks which the student is using at the time when he gains his first acquaintance with these organs in the dissecting room. A closer association of pure with applied anatomy is, moreover, at the present time more than ever desirable, a condition which can only be attained by a combination of a professed anatomist working hand in hand with surgeons or physicians who are actively engaged in professional work.

In conclusion we should like to express our high appreciation of Professor Frazer's valuable contributions to the manual, and more especially the permanent record which he has made in it of so much of his life's work on human embryology. *Buchanan's Anatomy* will be a valuable help, not only to the student as an introduction to the study of anatomy, but also to teachers and practitioners.

BRIGHT'S DISEASE

Bright's Disease and Arterial Hypertension. By Willard J. Stone, B.Sc., M.D., F.A.C.P. (Pp. 352; 31 figures. 22s. 6d. net.) Philadelphia and London: W. B. Saunders Co. 1936.

In this useful book Dr. Willard J. Stone has correlated his notes on the course and progress of his patients with Bright's disease with the literature of the subject. It is found that the diseases of which he treats occupy the third place among the causes of death in the United States. The author is clinical professor of medicine in the University of Southern California, and his book lays main emphasis on the clinical features of the groups of cases which make up the disease. In the past the clinician has often been too much dominated by anatomical and histological considerations, or, on the other hand, has adopted a purely clinical classification without reference to the underlying pathological state. The author has found useful a division of Bright's disease into acute and chronic forms with certain subdivisions. Among the acute forms there may be the usual haemorrhagic type or an acute degeneration following diphtheria, pregnancy, or septicaemia. The chronic forms are arteriosclerotic with primary hypertension, haemorrhagic with secondary hypertension, and degenerative. The discussion of these groups in detail, with a series of illustrative cases, is preceded by chapters on the physiology of the kidney and estimation of renal function. The main symptoms of Bright's disease are dealt with, the phenomena of water balance in the body and its upset in oedema, acidosis and alkalosis, and uraemia. All this is readable and up to date.

The main part of the book comprises a detailed description of the clinical features of renal disease, and may be recommended as a fair discussion of present-day knowledge. The photomicrographs of typical kidney lesions collected at Pasadena Hospital under the author's supervision illustrate well the anatomical basis of the various forms.

THE AUTHOR OF THE PURPLE ISLAND

Phineas Fletcher: Man of Letters, Science and Divinity. By Abram Barnett Langdale. (Pp. 230. 15s. net.) New York: Columbia University Press; London: H. Milford, Oxford University Press. 1937.

The Purple Island is full of interest to medical men, yet few have read it and fewer still could pass an examination on the life of Phineas Fletcher (1582–1650), who wrote the poem. Isaac Walton recommended him "as an excellent divine and an excellent angler. The author of the Piscatory Eclogues in which you shall see the picture of this good man's mind, and I wish mine to be like it." But it is *The Purple Island* which is of especial interest to doctors, for it deals allegorically with anatomy and physiology, and it would be interesting to ascertain how Fletcher came by the knowledge of his facts. Mr. A. B. Langdale points out that it contains things new and old. Phineas was almost exactly contemporary with Dr. William

Harvey, the discoverer of the circulation of the blood; both came from Kent, both were educated at Cambridge, Harvey at Caius, Fletcher a Fellow of King's College. Did they know each other and did Fletcher owe anything to Harvey? Mr. Langdale gives a fair summary, but only incidentally. In the Common Rooms at Oxford and Cambridge there was much good scientific talk during the first half of the seventeenth century. The Reverend John Ward, vicar of Stratford-on-Avon, records in prose some of the things he heard at Christ Church: Fletcher may have chosen to throw his recollections into a more poetical form.

The greater part of Mr. Langdale's book deals with the lineage, life, and surroundings of Phineas Fletcher. For this purpose he has gone to original documents for information, and has visited the villages and places where Fletcher worked and drew his inspirations as a poet, first in Kent, then at Cambridge, and finally in the Fen country. The result is most satisfactory. Phineas is no longer *nominis umbra*, but emerges as a somewhat quarrelsome parson and poet of genius who was indebted to Virgil, Ovid, and Spenser. Mr. Langdale is just but rather unkind when he gives in one appendix, "A Tabulation of the Passages in Fletcher's Works revealing Self-repetition," and in another, "The Apparent Sources of Occasional Passages in Fletcher's Works." There is a good bibliography and a sufficient index.

CHRONIC MILIARY TUBERCULOSIS

Chronic Miliary Tuberculosis. By Clifford Hoyle, M.D., M.R.C.P., and Michael Vaizey, M.B., M.R.C.P. (Pp. 140; 18 figures. 12s. 6d. net.) London: H. Milford, Oxford University Press. 1937.

Dr. Hoyle and Dr. Vaizey have had the opportunity of following up ten patients who, on clinical grounds, appeared to suffer from chronic miliary tuberculosis. In only one of the fatal cases, however, was a necropsy carried out. This form of tuberculosis, though extensively studied abroad since 1923, particularly in France, Germany, and Spain, has up to quite recent times attracted no attention in this country. Hoyle and Vaizey therefore undertook the laborious task of reviewing the whole literature of the subject. From the reported cases they collected 110 which to them appeared genuine examples of the condition. The attractively produced little monograph thus contains full details of their own cases and brief notes of the others. Basing themselves on these 120 cases, they describe the clinical and radiological features, the laboratory investigations, the clinical and radiological course, and the morbid anatomy and physiology. They then discuss diagnosis and treatment.

When it is realized that many tuberculosis workers still believe that miliary tuberculosis is rapidly fatal, and that a chest skiagram showing "miliary shadows" amounts to a death verdict for the patient, it will be admitted that the authors deserve our thanks for bringing chronic miliary tuberculosis so effectively into the clinical field in England. But there is at the same time a real danger in the publication of their work as a monograph. Chronic miliary tuberculosis is but one rare form of chronic disseminated tuberculosis, which in some degree or other plays an important part in the natural evolution of tuberculosis as a disease in nearly every individual. The danger, therefore, is that the effect of this book may be to focus attention not on the study of the development of the disease as a whole and on the importance of the chronic disseminated phase, but on the clinical aspects of chronic miliary tuberculosis alone.

To one error in the book we must draw attention. Pagel and Henke did not "emphasize minute cavities as a particular feature"; what they described was a special form of chronic disseminated tuberculosis associated with extensive small emphysematous bullae caused by the shrinking miliary nodules. This is so distinctive that Pagel has given a separate name to this condition—"disseminated emphysematous tuberculosis."

Notes on Books

A second edition has now appeared of Sir LANCELOT BARRINGTON-WARD'S *Abdominal Surgery of Children* (H. Milford, Oxford University Press, 25s.). This well-produced book, founded on the author's work at the Hospital for Sick Children, Great Ormond Street, was reviewed on its first appearance in our issue of March 31, 1928. Some chapters have been rewritten, others amplified, and all have been revised. Brief appendices now appear on anaesthesia and on intravenous saline therapy, the one by Dr. Niel McDonald, the other by Mr. J. C. R. Hindenach.

Volume i of the official *Report of the Ninth International Congress of Military Medicine and Pharmacy* has now been published. It contains the papers read at Bucarest last June and summaries of their contents in various other languages are appended. The topics dealt with in this volume include: the organization and functioning of the health services in combined operations by land and sea forces; the transport, hospitalization, and treatment of gas casualties; the organization and functioning of the surgical service in the case of mobile troops; the employment of colorimetric methods in analytical investigations in laboratories; the question of the dentally inefficient in peace time and warfare, including the provision of dentures and other treatment; and the special methods of feeding the sick and wounded required by various circumstances arising both in peace and in war. This volume presents a comprehensive review of modern methods of dealing with some urgent questions of the day, and is of unusual importance even outside the medical circles of the fighting forces.

Principles of Pharmacy, by Professor H. V. ARNY and Dr. R. P. FISCHELIS, is a well-established textbook; it first appeared in 1909, and has now reached a fourth edition (W. B. Saunders, 35s.). This volume of some 1,000 pages is divided into six parts, which deal with pharmaceutical operations, the galenical preparations, inorganic and organic chemistry, pharmaceutical tests, and dispensing. It thus provides a systematic survey of the knowledge needed by the student of pharmacy. The short history of pharmacy contains an interesting analysis of the American drug bill. The total bill is estimated at 715 million dollars. Drugs dispensed by hospitals and doctors account for only 7 per cent. of this total, while drug store sales are reckoned as 87 per cent., one-quarter of the latter representing the sum spent on prescribed remedies, and three-quarters that spent on self-medication. The sale of "patent medicines" in the U.S.A. is estimated at 335 million dollars. The final section, on dispensing, also contains much of common interest to the professions of medicine and pharmacy, since it discusses at some length the dispensing of illegible prescriptions and of prescriptions containing hopeless incompatibilities or probable errors in dosage. In general the volume gives a very clear account of its main subject and much information in a wider field.

The Johns Hopkins Press of Baltimore has reprinted the German original of Paul Langerhans's *Contributions to the Microscopic Anatomy of the Pancreas*, with an English translation and introductory essay by Dr. H. Morrison. The price of the book is 4s. 6d., and it is obtainable in this country from the Oxford University Press.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 28 1937

RAMON Y CAJAL: HIS CONTRIBUTION TO MEDICINE

The recent issue by the American Philosophical Society of Santiago Ramon y Cajal's autobiography, translated into English by Dr. E. Horne Craigie,[1] should appeal to a far wider circle of readers than that composed of neurologists and laboratory workers. The story is one of a man of exceptionally strong personality, who forced his way into international fame, in spite of an unfavourable environment, by unremitting toil controlled by the full power of his intelligence. It is not to be inferred, however, that the acquisition of fame was the goal of his ambitions; it was a by-product that often caused some anguish of mind when, by the award of some high international honour, his work was badly interrupted. Cajal's love of country nevertheless compelled him to accept such honours, and even, in the earlier stages of his career, to seek recognition abroad when he found that papers published in Spanish were not read by the medical world.

For lack of space the fascinating story of Cajal's life cannot be outlined here. The first volume of his autobiography is devoted to his early life, and in it he describes his boyish escapades and his harsh upbringing as well as many interesting details of life in Spain. His career might be said to have started when in 1877 he was installed at Zaragoza as auxiliary professor in anatomy and began to turn his attention to histology. It is astonishing to learn that teachers in biology and pathology habitually disregarded the microscope at that time, the instruments being kept carefully locked up in their cases. It is characteristic of Cajal that he not only used the microscope fully, but spent his hard-earned savings in buying the best instrument available. His interest in the histology of the central nervous system was shortly afterwards aroused when Simarro, the famous neurologist of Valencia, showed him some Golgi preparations. Cajal was already an amateur photographer of much ability, and it may be assumed that his knowledge of the chemistry of silver salts inspired his application of this new metallic method to the problems of histology. At all events he wasted no time in trying it in his own laboratory and in carrying it through modifications that yielded finer results than any obtained before. In particular he found that embryological material provided especially beautiful and clear results. Publications now followed one another in rapid succession. Unfortunately, however, these attracted little attention abroad, and their author realized that he must make his results known by other means. A vital step was taken in 1889, when he demonstrated his preparations at a meeting in Berlin of the German Anatomical Society. He describes how the supercilious attitude of the gathering towards a mere Spaniard and his work was transmuted to admiration through the single-minded generosity of Kölliker, who, in spite of his age and supreme eminence at that time, could take the trouble to examine and appraise the work of this newcomer. The support of this great man was of the greatest consequence: it meant acceptance by the world outside Spain, and Cajal's public was assured for all future publications. Honours followed—the Croonian Lectureship in this country in 1894, accompanied by the conferment of an honorary degree at Cambridge, and a lectureship in the United States in 1899 form but a small part of the distinctions which culminated in the award of the Nobel Prize in 1906. Cajal died in 1934 at the age of 82.

His contribution to medical science falls into two main divisions. First and foremost stands his work on the histology of the nervous system. He demonstrated this with a clarity that had never before been achieved, using modifications of the silver technique introduced by Golgi. The theoretical consequences of this work were of great significance. His results led Cajal to endorse wholeheartedly the neurone theory of Waldeyer, the supporters of which held that the propagation of the nervous impulse took place through contact between the processes of adjacent neurones. This was opposed by the supporters of the so-called "reticular" hypothesis, which postulated that propagation of the nervous impulse depended upon the continuity of cytoplasm between neighbouring neurones, which thereby formed a kind of syncytium. The controversy between these two schools was long and bitter; it was largely due to Cajal's vigour and the precision of his results that the neuronist eventually held the field. Much of the argument centred around the changes which take place in the nerve fibres in Wallerian degeneration and the subsequent regeneration of these fibres. This subject was studied in minute detail by Cajal,

[1] *Recollections of My Life: Santiago Ramon y Cajal.* Memoirs of the American Philosophical Society, vol. viii, Parts I and II. 1937. London: H. Milford. (22s. 6d.)

and we are fortunate in having an English version of this work.[2] It is well known that regeneration of nerve fibres fails to take place within the central nervous system: the abortive attempts made towards this end and the regression of the sprouts put forth from the central stump are described in these two volumes.

The structure of the neuroglial elements of the central nervous system and their demonstration by the famous gold chloride sublimate method are perhaps more often associated with Cajal's name than his earlier studies on the neurones, although it is clear from his autobiography that the latter were regarded by him as his principal achievement. However, the application of these new glial methods to embryological material revealed a series of developmental changes in the morphology of the neuroglial cells that was later adapted by Bailey and Cushing to the study of the gliomata. It was found possible to classify these tumours into types corresponding to stages in the embryological development of the neuroglia, a brilliant piece of work that has proved to be of practical as well as of academic importance, since upon it depends all modern work in neuro-surgery. It has now been abundantly demonstrated that both prognosis and treatment of the gliomata depend upon histological identification of the tumour disclosed at operation; some require radical removal whilst others are better treated by irradiation.

The last stages of Cajal's career saw him established as an acknowledged master with a school of energetic and often brilliant pupils in a magnificent institute provided by a grateful Government. In the present unhappy state of Spain all this has inevitably come to a standstill. We can only hope that means will be found to rebuild the splendid new school when fighting comes to an end, and that this revival may come soon.

THE INTERVERTEBRAL DISKS AND BACK PAIN

As a result of man's erect posture the spine is subject to exceptional stresses and strains. It must be strong and at the same time supple, a requirement which has been met by the specialized structure of the intervertebral disks. These disks are made up of three components: (1) cartilage plates adapted to the upper and lower surfaces of adjacent vertebral bodies; (2) the fibrous annulus; and (3) the nucleus pulposus, which represents the remains of the chorda dorsalis (notochord) and is enclosed by the fibrous ring. In 1896 Theodor Kocher[1] reported a case of rupture of the intervertebral disk between the first and second lumbar vertebrae in a young man who had succumbed to multiple injuries after falling from a height of one hundred feet and landing in the standing position. There was no fracture of the spine. This was one of the first cases to arouse interest in intervertebral disk lesions. A comprehensive radiological study of the chief lesions which we now know to affect the disks has recently been made by A. Craig Mooney.[2] One of the most interesting of these lesions, and one that has attracted much attention recently, is the extrusion of disk substance into the spinal canal. The extrusion consists of a herniation of nuclear tissue through a fissured annulus. The restraining action of the posterior longitudinal ligament affords some protection to the contents of the spinal canal, but this is not always enough: the herniation may project into the canal and, becoming vascularized from the spongiosa of an adjacent vertebral body, undergo calcification or ossification.

Herniation of the intervertebral disk has been recognized only quite recently, though for many years cases have been recorded in which the spinal cord has been compressed anteriorly by what have been regarded as chondromas originating in the intervertebral disks. Masses projecting backwards into the neural canal have also been variously described as myxochondromas, fibromas, loose cartilages, fibrochondromas, Schmorl's nodules (Knorpelknötchen), etc., and it is highly probable that all of these have in reality been examples of disk herniation in which the extruded pulposus has, in some cases at least, undergone secondary changes. Alajouanine and Petit-Dutaillis[3] drew attention to the condition in 1930. In 1934 W. J. Mixter and J. S. Barr[4] of Boston, Massachusetts, gave an account of nineteen cases of herniation of the nucleus pulposus into the spinal canal with compression of the cord or cauda equina. In the same year M. M. Peet and D. H. Echols[5] reported two further cases, and more recently W. J. Mixter and J. B. Ayer[6] have collected a series of thirty-three examples of the condition. Further accounts are also given this year by J. S. Barr[7] and P. C. Williams.[8] The commonest site of the lesion is between the fourth and fifth lumbar vertebrae. The patients present themselves with low back pain and loss of mobility of the lower part of the spinal column, symptoms which

lead these patients more frequently to the orthopaedic clinic, the physician, or the gynaecologist than to the neurological surgeon. There may be complaint of pain radiating into the buttock and down the leg suggestive of sciatica, and sensory and motor signs so slight as to be overlooked, with little more than some loss of sensation and a depression of the ankle-jerk. A curious clinical feature is the fact that the symptoms are not constant and that remissions occur. Pain is the most constant and prominent symptom, and it has been suggested that although the disk itself has no nerve supply the posterior longitudinal ligament, which takes the strain, is supplied with sensory nerve fibres. Diagnosis is confirmed by cerebrospinal fluid studies and radiography after the introduction of lipiodol—by a technique which requires the use of a larger quantity of oil than usual and a tilting *x*-ray table. It is noteworthy that plain *x*-ray photographs of the spine generally fail to show the abnormality.

An important question is the relation of this condition to injury. A rupture of the annulus fibrosus or of the cartilage plate must presumably take place before extrusion of the nucleus pulposus can occur, and a history of antecedent injury was obtained in nearly 80 per cent. of the cases from the Massachusetts General Hospital. Mixter and Ayer remark that the discovery of this new clinical and pathological entity introduces a fruitful source for industrial and accident compensation. The most common cause of injury in the recorded cases has been the lifting of heavy weights, and injury to intervertebral disks has also been reported by C. N. Pease[9] as a result of lumbar puncture. Paraplegia has followed spinal manipulation of these cases, presumably by increasing the herniation. Any attempt, therefore, to suggest that this disk herniation may be that pathological process undemonstrable by *x* rays but held by the osteopaths to be the basis of their practice and corrected by it is quite untenable. Treatment by laminectomy and removal of the herniated mass, either by an extradural or intradural route is claimed to give uniformly good results. Spinal fusion may also be required if the laminectomy has been extensive and has necessitated the removal of one or more of the articular facets. Among the large group of patients variously labelled as cases of radiculitis, lumbago, sciatica, fibrositis, myalgia, and backache of apparently gynaecological origin it is not improbable that some may be suffering from disk lesions. Many of these patients with low backache are a bane to the life of a busy practitioner, and he should bear in mind the possibility that the lesion causing the pain may be herniation of a disk.

THE PANCREATROPIC HORMONE

The presence in the anterior lobe of the pituitary of hormones which act on the other ductless glands is now generally recognized, but it is by no means clear what effect the pituitary has on the pancreas. One group of workers hold that an anterior pituitary hormone stimulates the islets of Langerhans and may even lead to an increase in islet tissue. Another group speak of a diabetogenic or anti-insulin hormone, and state that pancreatic diabetes (in depancreatized animals) will not occur in the absence of the anterior pituitary. The former group claim to have demonstrated that injection of anterior pituitary extracts produces a fall in blood sugar and a multiplication of islet cells. The significance of such a finding, if confirmed, is obvious. According to one view the islet cells, once they have developed during foetal life, lose all relation to the surrounding parenchyma and lead a separate existence as true endocrine glands, with a layer of connective tissue separating them from the acinar cells of the pancreas. Another view is that the islets arise by differentiation of pancreatic acini, that they function for a time as endocrines, and later return to their previous exocrine function. Yet a third theory regards the islets as arising from the centro-acinar cells of the pancreas. The histologist Maximow says: "It seems fairly well assured that the pancreas, even in the adult, is provided with undifferentiated cells which can give rise to new acini and, to a great extent, to new islands." Morphologically, therefore, there is no strong reason why new islets should not be formed in the diabetic—unless it is just this power of regeneration which is lost. Anselmino and Hoffman, in their original work, used extracts of fresh anterior pituitary lobes and obtained rapid new formation of islets and increase in size of those already present; but they did not indicate whether the new formation was due to metaplasia of acinar cells or to division of already existing islet cells. In a recent publication Chrzanowski and Grzycki[1] report results obtained from the injection into rats of aqueous extracts of anterior pituitary. Such extracts produced no effects on either the islet or the acinar tissue of the rat pancreas, nor was there any evidence of the new formation of islets. But on passing the aqueous extracts through an ultrafilter and treating the ultrafiltrate with an acetate buffer solution of *p*H 5.2, and submitting it to further ultrafiltration, they obtained a filtrate which on neutralization had a marked effect on the rat pancreas. A few injections produced a loss in the normally sharp contours of the islets, with a definite increase in islet tissue. The authors state that under the influence of these injections there was clear evidence of new formation of islets, and adjoining ones could be seen in the process of joining together by a bridge of newly formed tissue, the latter rapidly undergoing mitosis until a giant islet was formed. The parenchymatous tissue appeared to be unaffected. The new islet tissue is stated to originate from certain isolated, lightly staining parenchymatous cells, and to a less degree from the centro-acinar cells. Chrzanowski and Grzycki attribute the inactivity of the aqueous extracts to the inhibitory

[1] *Klin. Wschr.*, April 3, 1937, p. 485.

action of another pituitary hormone, probably the anti-insulin hormone described by Lucke, which can be separated from the pancreatropic hormone by ultra-filtration. These results, in essence, confirm the claims of Anselmino and his co-workers. It is interesting, however, to note that another communication from the same university[2] categorically denies that extracts of beef pituitary, prepared by the method of Anselmino and his colleagues, contain a pancreatropic hormone. The extracts were administered twice a day to rats, guinea-pigs, and rabbits for periods up to eight days, and the blood sugar and the histology of the pancreatic islets were both studied. In no case could evidence of a pancreatropic hormone be obtained, and the authors ascribe the findings of other workers to the variability of the form and distribution of the islets. As to the production of giant islets, they state that these are found in the glands of untreated animals. It is clear that the difficulty is one of rigid control, but the weight of evidence would seem to be on the side of those who claim the existence of the pancreatropic hormone.

NERVOUS MECHANISMS IN ANGINA

In the differential diagnosis of coronary occlusion pulmonary embolus has sometimes to be considered, for pain or oppression in the chest, dyspnoea, cyanosis, and shock are common to both. A previous history of effort angina would suggest myocardial infarction; and any obvious thrombophlebitis or a recent abdominal or pelvic operation would support the diagnosis of pulmonary embolus, as also would the predominance of dyspnoea and cyanosis over pain. The electrocardiogram may also help, but it is well known that in pulmonary embolism it may show changes indicating altered myocardial function. It is held by D. Scherf and E. Schönbrunner[3] that these result from a reflex coronary constriction from impulses arising in the lung and conveyed along the vagus, and apparently on their view the discomfort or pain in the chest is due to coronary constriction. Explanation of these effects on the basis of anoxaemia caused by the pulmonary obstruction is rejected, as they claim to find changes in the electrocardiogram even with a small embolus. In experiments on ten dogs they found alteration of the T-waves after lung embolism in three, alteration of the QRS complex in four, and no change in the remaining three. Division of both vagi before the experiment is said to prevent any change in the electrocardiogram, and also to lessen the severity of the symptoms after pulmonary embolism. The practical application of this work is, according to the authors, in the use of nitrites in pulmonary embolism to relieve coronary spasm resulting from the pulmo-coronary reflex. Confirmation of Scherf's and Schönbrunner's observations appears desirable before their recommendation is accepted. Observations after total thyroidectomy in cases of severe angina throw some light on the nervous pathways concerned in this condition. That pain was relieved so soon after operation that it could not be attributed to a lowered metabolism suggested that injury to some of the cardiac nerves in the neck accounted for this—an explanation that was strongly supported by the fact that after hemi-thyroidectomy the relief was limited to the operated side. A clinical investigation of the problem and anatomical dissections to determine the nervous relations of the thyroid gland have been made by A. A. Weinstein and H. E. Hoff.[4] In three patients they mapped out areas of superficial and deep hyperaesthesia on the chest wall, and by constant testing during operation under local anaesthesia they demonstrated that this hyperaesthesia disappeared either at the moment the gland was shelled out from its bed, when the inferior thyroid vessels were ligated, or when the stellate ganglion was injected with novocain. The choice of patients for this demonstration does not seem to have been very suitable: all three had rheumatic heart disease; only one had angina; and the other two were suffering from congestive failure. The dissection carried out on sixteen cadavers showed that in 70 per cent. the superior cardiac nerve, arising from the superior ganglion of the cervical sympathetic, was closely applied to the posterior surface of the thyroid gland, and that in 20 per cent. the middle cardiac nerve either lay on the gland or was close to the inferior thyroid vessels. Both these nerves are believed to carry afferent fibres from the heart, and their division or injury during thyroidectomy would serve to explain the amelioration of anginal pain sometimes observed immediately after operation. However, like the anatomical relations, the relief is inconstant, and moreover only temporary, either because of recovery in injured nerve fibres or because of compensation by alternative routes. The observations throw light on the nerve paths concerned in angina, although it is clear that they give no encouragement to operations on the cervical nerves undertaken deliberately for the relief of this condition, and such methods have now been generally abandoned.

LICHEN URTICATUS

Few children pass through their infancy without suffering to some slight degree from "heat spots," and in a great many cases these lesions are sufficiently numerous and persistent to call for medical advice. This eruption, which is one of the plagues of childhood, has been labelled with many different names, but the two under which it is most commonly known are lichen urticatus and papular urticaria. The problems of its aetiology and treatment still remain unsolved. It has often been designated teething rash by the lay public, but there is little evidence that it is caused by teething, which is after all a physiological and not a pathological process. Many attempts have been made to prove that it is due to dietetic errors; in fact, it is sometimes known as chronic alimentary urticaria; but this theory is by no means proved, and its various supporters differ greatly in the importance which they ascribe to various factors. Some regard it as due to the ingestion of an excessive amount of carbohydrates; others to proteins; and it has been held that breast-fed infants never suffer from it. These different theories are mutually contradictory. One factor there is that has an undoubted influence—that is, temperature. All observers are agreed that the

[4] *Surg. Gynec. Obstet.*, 1937, 64, 165.

eruption is much commoner in summer than at any other time of the year, and Hallam has been able to obtain in almost every case complete remission of the eruption, however severe, merely by taking the children into hospital even although they continued to be supplied with their ordinary diet by their parents. It is suggested by Tate that the explanation of the benefit of merely sleeping in hospital is the fact that hospital wards are commonly kept at a much lower temperature than many private dwellings. For many years workers have striven to establish some connexion between lichen urticatus and calcium metabolism, and calcium in various forms has been a favourite remedy with many paediatrists. The results of this treatment, however, have been by no means satisfactory. In recent years it has been established that the parathyroid gland is intimately concerned with calcium metabolism, and Drs. Pilsbury and Sternberg[1] report considerable success in the employment of parathyroid extract given subcutaneously in doses of 10 to 25 units at weekly or bi-weekly intervals. At the same time they also administered internally calcium lactate, calcium gluconate, or dicalcium hydrophosphate, and the usual forms of local treatment. They claim good or excellent results in 85 per cent. of their cases, while in another series in which parathyroid extract was not given only 38 per cent. responded satisfactorily. They ascribe these results to an elevation of the level of the calcium content of the blood and consider that such increase in blood calcium may either produce a sedative effect or may correct some underlying fault in calcium metabolism. They discuss in some detail the theory that the nature of the disease is allergic, but they consider that the evidence in support of such a view is extremely meagre.

HEALTH IN THE UNITED STATES

A recent Bulletin issued by the Health Organization of the League of Nations[2] contains a report by a group of European experts in hygiene setting forth impressions which they gained in the course of a visit to the United States during 1935. The report is mainly concerned with public health in its relation to social problems which have lately been engaging the attention of administrators in the Union. After an introductory reference to the geographical, economic, racial, and other features of the country, notice is taken of the prevalence of certain disease conditions, and the recommendations of the Committee on the Costs of Medical Care are cited. The Federal, State, and local authority agencies for the protection of the public health are passed in formal review. It is observed that in America compulsory pasteurization does not meet with such strong opposition as it has encountered in Great Britain and Denmark. During their stay in Chicago the visitors were confronted with sanitary problems which were new to them, including the existence of by-passes between pure and raw water supplies. Of the articles devoted to selected topics one is concerned with the social security movement, the need for which was thrown into high relief by the economic depression which reached its crisis in 1933. In this connexion the report quotes President Roosevelt's message to Congress. "People," he said, "want decent homes; they want to locate them where they can engage in productive work; and they want some safeguard against misfortune." A committee appointed by the President made useful recommendations, which were substantially incorporated in the Social Security Act of 1935. This Act established a system of Federal grants to States for the promotion of welfare services not only by way of old-age pensions and unemployment allowances but also, in the domain of health, by the development of maternity and child welfare activities and of schemes for crippled, homeless, and neglected children. It made provision also for assisting States and local authorities to establish and maintain adequate general public health standards, including the training of personnel for State and local health work. Another article in the report deals with the teaching of preventive medicine in the medical curriculum. It is stated that there is in America a lively appreciation of the importance of instruction of this kind, but that in the time available to the visitors it was difficult to determine to what extent the idea received practical application. The medical examination of entrants, they say, as carried out at some universities, followed by periodical examinations, may convey to the student's mind some dim suggestion of a preventive purpose, but at certain American medical schools special methods have been devised to bring him face to face with the morbific environment of the patient upon whose case he is preparing his clinical report. He is made to demonstrate to himself that, given adequate preventive measures, his patient in all probability would not have been stricken at that time with the particular disease from which he is suffering. The report adds that this method of "clinical case studies," as it has been called at Vanderbilt and Yale, has had the remarkable effect of inspiring the student of medicine at these universities with enthusiasm for public health.

THE EDUCATIONAL NUMBER, 1937

No. 4000 of the *British Medical Journal*, dated September 4, 1937, will be the annual Educational Number. Its contents, as in previous years, will include a full account of the requirements of the General Medical Council and of the universities and other licensing bodies in Great Britain and Ireland, as well as information about the opportunities offered by the various medical schools and other teaching institutions and the fees charged by each. The details given have been revised and brought up to date by the authorities concerned. These sections, the object of which is to furnish a handy guide to intending students of medicine, are supplemented by articles intended for newly qualified practitioners on such matters as postgraduation study (with special reference to the British Postgraduate School at Hammersmith), the public medical services at home and abroad, tropical medicine, psychological medicine, and the various special diplomas. The opening article for our forthcoming Educational Number, written by Sir David Wilkie of Edinburgh, is entitled "Education in Surgery for General Practice."

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

LOCAL ANAESTHESIA

BY

C. W. MORRIS, O.B.E., M.B., B.S., D.A.

The outstanding feature of local anaesthesia is that it enables a patient to undergo an operation without loss of consciousness—a feature shared with spinal anaesthesia. It is obvious that the retention of consciousness may be both an advantage and a disadvantage. Local anaesthesia, however, supplies the best answer to the patient suffering from some minor surgical complaint who states that he is perfectly willing to undergo the operation but cannot face a general anaesthetic. Owing, however, to the great progress made in recent years in general anaesthetics, in which both the safety and the comfort of the patient have been increased, the employment of local anaesthesia has become somewhat restricted.

With the exception of certain special conditions local anaesthesia finds its chief usefulness in minor surgery. For this reason it is invaluable to the general practitioner. This does not imply that it should be limited to minor surgery, as it is safe to state that every operation can be, and has been, performed under this form of anaesthesia. It still can be regarded as a useful alternative to general anaesthesia for most operations and the anaesthetic of choice for many. A local anaesthetic may with advantage be employed in the following circumstances.

1. Used alone, or after preliminary medication with morphine and hyoscine, in minor surgical conditions such as removal of sebaceous cysts, adenoma, lipoma, excision of scars, removal of small foreign bodies, etc.

2. In more extensive operations: (*a*) when the patient dreads a general anaesthetic; (*b*) when the patient's condition is such that a local anaesthetic would be less dangerous than a general.

3. In combination with general anaesthesia to obtain relaxation and lessen the amount of general anaesthetic given.

4. When the practitioner is single-handed and has to act as both anaesthetist and surgeon.

Contraindications include such conditions as sepsis round the site of the injection and patients who dread being "awake" during an operation. Young children are not considered good subjects, although it is interesting to note that a local anaesthetic is advocated for Rammstedt operations.

Among the advantages are ease of administration, absence of extensive preparation of the patient, freedom from unpleasant after-effects, and last, but by no means least, safety. The surgeon must remember that the patient is not unconscious and that the area of anaesthesia is limited; gentleness must therefore be of the highest order.

Local Anaesthetic Agents

Many drugs are available which appear to give good results. As my experience has been chiefly with novocain that drug only will be referred to here. It may be used in dilutions of 1/2 per cent. to 2 per cent., and unless otherwise stated it will be assumed that 1/2 per cent. is the strength referred to throughout this paper.

Novocain solutions can be repeatedly boiled for sterilization and as much as 200 c.cm. of the 1/2 per cent. solution be injected with safety. The addition of adrenaline hydrochloride (1 in 1,000) in the proportion of three drops to each fluid ounce of the solution gives two advantages: the duration of the anaesthesia is increased, and there is less haemorrhage in the field of operation. Where adrenaline may be harmful on account of its action on the circulation, as in toxic goitre, novocain and "cobefrin" may be used. "Cobefrin" is claimed to have no adverse effect on the circulation, and certainly produces a satisfactory ischaemia.

Instruments and Method

A good syringe capable of being sterilized—one of 10 c.cm. capacity is a handy size—and an assortment of needles ranging from fine hypodermics to those of from two to three inches in length are needed. Longer needles may be used but they are rather more difficult to direct. A "continuous-flow" type of syringe saves time when an extensive area requires infiltration.

Local anaesthesia may be produced by (1) local infiltration, (2) nerve blocking, or (3) a combination of the two. Before the injections are started the patient, if at all nervous or if the area to be infiltrated is extensive, should be given a hypnotic. For adults morphine 1/6 to 1/4 grain or omnopon, if preferred, combined with hyoscine 1/150 grain will prove helpful. The more powerful basal narcotics, as avertin or nembutal, are not as useful as one might suppose, for should the patient be only lightly under these drugs he may resent the discomforts of the infiltration and become restless and difficult to control. The area to be infiltrated, the syringe, needles, solution, and the hands of the anaesthetist must be prepared with the care that is given to any surgical operation.

First of all a wheal is raised in the skin with a fine hypodermic needle at the proximal end of the area requiring anaesthetization; through this wheal a larger and longer needle is thrust and the infiltration carried on under the skin. If the infiltration is done gently and slowly the discomfort is reduced to a minimum. In loose skin the area of subcutaneous infiltration can be followed with ease and the exact spread of the solution accurately determined. Subsequent insertions of the needle should always be through the anaesthetic area, so limiting the pain to the first prick of the hypodermic needle.

While infiltrating, care must be taken to avoid direct injection into the circulation. This may be guarded against by taking the following precautions. As the needle is pushed forward under the skin the plunger should be pressed down to send a stream of the solution before the needle point. This will tend to push aside small vessels and lessens the possibility of injection into their lumen, or of causing a haematoma. When in the proximity of large vessels the plunger should be withdrawn slightly from time to time to see that no blood is aspirated into the syringe. Perhaps the safest way is to thrust the needle to the limit of the area and infiltrate only while it is being slowly withdrawn. It is possible that the failure to observe these precautions have been responsible for the rare accidents which have been reported.

For conditions such as small cysts, or when skin incisions only are required, a single broad line of infiltration is all that is necessary. For larger tumours an elliptical area surrounding the tumour must be infiltrated

and some of the solution placed deep to it as well. A liberal amount of the novocain solution will contribute to the success of the anaesthesia. When a large area has been treated in this way a short wait of from ten to fifteen minutes before operating will allow the solution to soak well into the tissues. Some anaesthetists advocate the gentle massaging of the infiltrated area to assist the diffusion. A pin or towel-clip can be used for testing the degree and extent of anaesthesia obtained and the result noted by watching the reaction of the patient's face. This is better than asking him whether he is hurt, as that suggests pain and increases his apprehension. This subcutaneous infiltration method may be elaborated and applied for a large variety of operations.

For fingers and toes the method is slightly changed; a nerve block is effected by ringing round the base of the digit. Here again a wheal is raised on the dorsal aspect at the base of the finger or toe and the circle of infiltration completed by employing a longer needle. In this case it is safer to use very little, if any, adrenaline with the solution, as the ischaemic effect of the adrenaline is very marked when injected in this way. I have seen a finger apparently bloodless when adrenaline had been injected, and although no ill effects followed, the risk of sloughing must have been considerable. After five to ten minutes the whole finger becomes anaesthetized, and a large number of minor operations may be carried out without pain to the patient. This method of anaesthetizing fingers must not be adopted in cases of whitlow when the inflammation involves the base of the finger.

When General Anaesthesia is Contraindicated

In the second class are included a large number of operations which may be performed under local anaesthesia owing to the condition of the patient contraindicating a general anaesthetic. In this class it is usual whenever possible to give a preliminary hypnotic. Some typical cases will be described.

RIB RESECTION FOR EMPYEMA

Here the patient may be seriously ill from an antecedent pneumonia, or pneumonia may still be present. The portion of rib to be resected is determined, and it is helpful to outline it with an indelible pencil. A wheal is raised at the dorsal extremity of this marked area and a two-inch needle is thrust down till its point touches the surface of the rib. The needle, detached from the syringe for greater mobility, is then pushed down till the lower border of the rib is detected, and the point is then directed into the subcostal groove; 5 c.cm. of the solution is then injected to block the intercostal nerve and render that segment of the chest wall analgesic. The periosteum along the outer surface of the rib is then infiltrated, and finally the skin along the proposed incision is thoroughly dealt with. The infiltration must be sufficiently wide to include the intercostal space both above and below the selected rib. Some three to four ounces of the solution may be necessary to produce complete analgesia.

One warning may be given to the surgeon. The rib must be cleanly cut through and no wrenching or traction made, else pain is transmitted to the unanaesthetized parts of the chest wall.

DRAINAGE OF BLADDER

Another example in this class is the drainage of the urinary bladder in cases of prostatic obstruction. Here again the patient may be in a condition in which a general anaesthetic is not considered advisable. A line of anaesthesia is laid down extending from just below the umbilicus to the symphysis pubis. The skin and fat are thoroughly infiltrated and the linea alba between the two recti injected, and the two muscles as well. As in all operations under a local anaesthetic, should the patient complain of pain while the operation is in progress a pause may be made and the sensitive layer or part directly infiltrated. If the opening of the bladder causes discomfort a syringe full of the solution can easily be injected into its wall.

GASTROSTOMY

An emaciated and cachectic patient undergoing an operation for gastrostomy may benefit by having it performed under a local rather than a general anaesthetic. A subcutaneous band of infiltration is placed along the left rectus muscle, starting from just above the costal margin and extending down to the umbilicus. The rectus sheath and muscle are deeply infiltrated, and an attempt is made to infiltrate the peritoneum below. Should this layer escape the solution and prove painful it may be directly infiltrated during the operation. The stomach wall does not require infiltration and the patient will complain of no pain while it is opened provided there is no undue traction. The solution should be used freely, and as much as four or five ounces may be necessary to obtain good anaesthesia.

TRACHEOTOMY

A tracheotomy or laryngotomy may be easily and quickly performed under local anaesthesia, and in some cases it may be the only anaesthetic that can be given with safety. For this purpose a 1 per cent. solution of novocain and adrenaline should be employed. A subcutaneous band of infiltration is placed down the middle line from the cricoid to the manubrium sterni. Before the trachea or the larynx is opened 1 c.cm. of a 10 per cent. solution of cocaine should be injected between the cartilaginous rings of the trachea, or in the case of a laryngotomy through the cricothyroid membrane. This will help to check the paroxysmal coughing that otherwise occurs when the tracheotomy or laryngotomy tube is first inserted.

THE INGUINAL REGION

For operations in the inguinal region, such as for herniae, varicoceles, and hydroceles, the following technique, slightly modified to meet each operation, will prove serviceable. The usual small preliminary wheal is raised at a point one and a half to two inches internal and above the anterior superior spine of the ilium. Through this wheal a larger needle is thrust downwards and outwards towards this bony point. Some 20 c.cm. are injected deeply under the aponeurosis of the external oblique and down between the internal oblique and transversalis muscles till the needle makes contact with the ilium. This should block the hypogastric branch of the ilio-hypogastric nerve and the ilio-inguinal nerves as they lie between these layers. Without withdrawing the needle from the skin its direction is now changed to lie parallel to Poupart's ligament, and some 20 c.cm. injected widely under the aponeurosis of the external oblique, and lastly the subcutaneous area reached through this puncture infiltrated. The needle is withdrawn and inserted through the now analgesic skin over the internal abdominal ring, and 20 c.cm. are injected under the aponeurosis through the internal oblique as it covers the inguinal canal and into the cord itself, infiltrating these structures thoroughly and blocking the genital branch of the genito-crural nerve. The subcutaneous area is injected last, as this enables the deeper infiltration to be more easily carried out. One more injection over the lower part of the inguinal canal

will reach the external abdominal ring, where the cord must be infiltrated as it crosses the pubis. On completion of the infiltration the patient should be allowed to lie quietly for some twenty to thirty minutes, while the solution is taking effect, before the operation is started.

Many operations, such as evulsion of the phrenic nerve in cases of active phthisis, colostomies or caecostomies in patients dangerously ill with obstruction, may be performed with advantage under a local anaesthesia, but space does not permit of giving details of each case.

OTHER CONDITIONS

In the third class mention may be made of blocking the lower intercostal nerves, as already described, with 2 per cent. novocain and adrenaline on one or both sides.

An extensive field blocking of the abdominal wall with 1/2 per cent. novocain and adrenaline may be combined with nerve blocking or employed alone. These measures should be carried out while the patient is under gas and oxygen, and when successfully performed contribute markedly towards obtaining muscular relaxation and so limiting the amount of ether or chloroform that has to be used.

Other uses of local anaesthesia include its employment in dental work and its recent application for injection of fractures, while cocaine or its substitutes are largely utilized for nose, throat, and eye operations.

The few examples of the application of local anaesthesia given in this article, while by no means exhaustive, may serve to show its value both to the whole-time anaesthetist and to the practitioner, and may encourage its employment by those who have as yet not been tempted to try it.

Local News

ENGLAND AND WALES

West Riding Medical Charitable Society

The one hundred and ninth annual meeting of this long-established Yorkshire charity was held at Harrogate under the chairmanship of Dr. Edgecombe. The objects of this society are to help medical men who have fallen on evil times and to give financial assistance to the dependants of members who die without having made provision for them. Of late years the society has interested itself to a greater extent than formerly in securing adequate education for the children of its members. In some twenty different centres of the West Riding one or two stewards are elected to report on the financial condition of the applicants for help, and in many cases they are able to give that personal information which is such a valuable supplement to mere documentary evidence. Any grants that are made are handed to the stewards, who are given discretionary powers in the dispensing of the money. Membership now numbers 1,261, and the financial condition of the society is very sound. The invested funds amount to £55,577, and the ordinary income is about £3,100, which represents the amount derived from investments and the one guinea annual subscriptions of members. At the annual meeting just held grants amounting to £2,713 were awarded, and a special grant of £50 was again made to Epsom College towards their fund for the provision of foundation scholarships for the sons of medical men. Dr. Wardrop Griffith, who has acted as honorary treasurer of the society for the last sixteen years, has resigned that position, and will be succeeded by Mr. Harold Collinson. At the end of the meeting the president, Dr. Edgecombe, asked Dr. Griffith to accept from the officers and stewards of the society an antique silver loving-cup as a token of their appreciation of his devoted service during his sixteen years' tenure of the office of treasurer.

Nutrition in Lancashire

The annual report for 1936 of the county medical officer of health and school medical officer to the Lancashire County Council Education Committee includes an interesting paper dealing with the nutrition of children at a council school. Some ten years ago a shop in the vicinity of this school greatly increased its turnover by providing fried chipped potatoes for children who were unable to go home for dinner. It then occurred to the head master to arrange for a well-cooked and varied midday meal at the school itself, and this scheme, by careful organization and by the delegation of the greater part of the housekeeping, marketing, and finance to the children, soon worked so smoothly that the head master found less than an hour a week to be adequate time for its supervision. The school in question serves a fair-sized village with a surrounding agricultural district. Medical surveys of 147 children, of whom rather less than a third were "school-fed," demonstrated that with the exception of one case these children were in better condition than the "home-fed." There were no badly nourished children in the "school-fed" group. The beneficial effect of the school midday dinner was most marked among the older children, who had in most cases been "school-fed" for two or three years. These striking results were obtained in a district where there is little poverty, and are attributed not to a calorific superiority but to a greater variety of diet in the school regime, for the home dinners were too frequently either stew or chipped potatoes. It is suggested that even more satisfactory results would be obtained by the application of this scheme in really poor districts.

Harlow Wood Orthopaedic Hospital

On July 28 Mr. R. H. Bernays, Parliamentary Secretary to the Ministry of Health, opened the new ward and extensions of the Harlow Wood Orthopaedic Hospital at Nottingham. These will provide twenty-one beds for male patients, rooms for about eight private patients, and additional accommodation for nurses. The total number of beds in the hospital is now approximately 155. Before the ceremony the eighth annual meeting of the hospital was held under the presidency of the Duke of Portland. The president of the hospital, the Duchess of Portland, in proposing the adoption of the annual report, said that the waiting list was larger than it had been at any time since the opening of the third ward three years ago. Mr. Bernays, in seconding the proposal, was impressed by the happy union of voluntary effort with support from employers, employees, and local authorities. He hoped that the progress made at Harlow Wood might be an incentive to the initiation of similar co-ordinated schemes in other areas. Mr. S. A. S. Malkin, supporting the adoption of the report, said that the Midland Colliery Owners' Mutual Indemnity Company had offered to give £5,000 as a contribution towards the provision of additional beds for the treatment of injured miners. This was an indication that what had been done in the past by the hospital had not only been beneficial to the men but had been a success from the financial point of view. Referring to co-operation between hospitals, he said that he hoped to see in the Nottingham area a grouping of hospitals with a joint contributory scheme, so that every patient could be admitted to the hospital best suited to deal with his or her case. Lieut.-Colonel G. A. Lewis, chairman of the Midland Colliery Owners' Mutual Indemnity Company,

handed to the president a cheque for £2,500, being the second instalment of the Company's gift of £5,000 for the provision of the new ward.

National Council of Social Service

The seventeenth annual report of the National Council of Social Service, 26, Bedford Square, London, W.C.1, has just been published under the title of *Voluntary Service* at the price of 1s. The report, which is well illustrated, gives among other things an account of the work it has done in promoting community centres in the new housing estates. It is now seven years since the National Council first took the initiative in forming a new estates community committee to consider the problem of social development in the new housing estates which surround the larger towns. It is pointed out that the evolution of the community life of the new housing estate cannot be effective without the participation of three agents: the local authority, the established voluntary bodies in the town, and the residents of the estate. It is reported that during the year no fewer than twelve local authorities have started schemes for community centres. Under the heading "The Challenge of Unemployment" the report refers to the need of the unemployed for organized help of the community, which may be given in many forms. The National Council is particularly concerned with that form which centres round the occupational club, of which there are now about 1,450 in England and Wales and Scotland. In these occupational clubs physical training has always had its place, and during the past year a special grant from the Ministry of Labour has enabled the National Council to develop it on a wider scale, a number of well-qualified instructors having been appointed.

Correspondence

The "Other Half" of Medicine

SIR,—The other day, at a psychiatric clinic where I work, I saw a patient suffering from a severe anxiety neurosis of nearly three years' duration. The documents attached to his case-sheet included a copy of a report from a distinguished physician on the staff of a well-known London teaching hospital, addressed to the patient's general practitioner, who had asked for advice. It ran as follows:

"I can find no evidence of organic heart disease in this case, and an electrocardiogram showed nothing beyond a simple tachycardia. Indeed, his symptoms could not possibly arise from the heart, and I agree with you that they are probably entirely of nervous origin. As you say, there may be some psychological factors at work which are the root of his trouble. I should favour reassuring him and continuing with the regular doses of bromide or luminal. Sometimes glucose taken between meals helps cases of this sort, and you might try it."

That type of logic surpasses belief. The case is a psychological one; therefore let us treat it by physical means! One did not have to be an orthodox Freudian to infer that the trouble might likely turn out to be psychosexual in origin on eliciting from the patient the information that he had his first anxiety attack on the day before his wedding (he had been "courting" for nine years). In the course of the interview it soon became clear that current and perfectly conscious and remediable sexual errors were responsible for the man's illness.

It is my belief that the advice which I gave to the patient and his wife will result in the spontaneous resolution of his symptoms within six months, without further psychotherapy. It is true that I spent an hour and a half on the case, and that it only takes a minute or two to prescribe bromide and luminal. But which is the better medicine?

In my introduction to my translation of Kretschmer's *Textbook of Medical Psychology* I said: "Medical psychology is not just a psychiatric 'sideline'—although it must provide the foundations for all sound psychiatric teaching—*but the 'other half' of medicine itself.*" That this truism is not appreciated by even the most distinguished exponents of the science and art of medicine in this country is a crying scandal. I should rejoice to be able to address the following letter to Dr. X:

"To-day I examined your patient, Mr. Smith. I agree with you that the patient is suffering from a (probably operable) cerebral tumour. I therefore recommend a course of psychoanalysis."

—I am, etc.,

London, W.1. E. B. STRAUSS.

Blood Alcohol and Drunkenness

SIR,—The question of the relation between the alcohol content of the blood and drunkenness has been much to the fore recently, and we have received a number of inquiries concerning the methods employed in determining blood alcohol. For some time past we have been investigating the extent to which figures for blood alcohol may be relied upon in assessing the extent of drunkenness, and, while this investigation is as yet incomplete, we feel that there are a number of points which it would be of value to bring to the notice of those interested in the subject.

First, there is the question of the method to be employed. There are two methods in common use: (1) Widmark's[1] micro-method, using one or two drops of blood; and (2) Southgate's[2] method, in which 2 to 5 millilitres (ml.) of blood are normally used. We ourselves use a modified Southgate apparatus and adapt the technique for either one drop or 2 to 5 millilitres of blood. It should be noted that the large-scale method is inherently more accurate than the micro-method. The Widmark method suffers from the drawback that the quantity of blood available is small. In all work of this nature both duplicate and control experiments must be performed, together with tests for interfering substances, such as acetone, so that the larger quantity of blood available for the Southgate method is preferable.

To illustrate the type of results obtained with our modified Southgate apparatus the following successive experimental determinations by both micro- and macro-technique are given. Alcohol content present in samples approximately 200 mg. per 100 ml.

Samples taken	Alcohol found
1. 0.1 ml. urine	202 mg. per 100 ml.
2. 0.1 ml. „	193 „ „
3. 0.135 g. blood	181 „ „
4. 0.146 g. „	176 „ „
5. 0.147 g. „	210 „ „
6. 0.152 g. „	186 „ „
7. 2.0 ml. „	187 „ „
8. 2.0 ml. „	187 „ „

Experiments 3 to 8 were performed on the same sample of blood.

[1] *Die theoretischen Grundlagen und die praktische Verwendbarkeit der gerichtlich-medizinischen Alkoholbestimmung.* 1932.
[2] *Biochem. J.*, 19, 737. (See also Evans and Jones, *Analyst*, 54, 135.)

Secondly, there is the question of material. Either blood or urine may be used, and it has been established that the ratio of alcohol in blood to that in urine varies narrowly about a mean figure of 1:1.35. In view of the common aversion of laymen to giving blood and the greater ease of collection of urine, especially in cases of drunkenness, we have found it very much simpler to work on urine. The quantity of urine available, moreover, makes it more easy to look for interfering substances.

Thirdly, it must be emphasized that it is the amount of alcohol absorbed into the blood which determines the extent of the intoxication rather than the absolute amount consumed. It has been established that part at least of the greater tolerance of the habitual drinker is due to his lower rate of absorption. Even taking this into account, it can be stated for any individual that a given blood alcohol concentration indicates a certain *minimum* alcohol consumption, and it is in this that lies the whole value of the test. The habitual drinker, of course, requires a larger consumption to produce a given concentration than does the occasional drinker.

Fourthly, there appears to be a feeling that certain cases will show strongly anomalous figures for alcohol concentration, and some people have an uneasy suspicion that they themselves might be regarded as under the influence of drink with a comparatively low alcohol consumption. We have not found this to be the case. It is generally accepted, and we have confirmed, that an alcohol concentration between 100 and 150 mg. per 100 ml. is the threshold concentration required to produce definite clinical symptoms of drunkenness. Our experiments all indicate that moderate consumption in an average person produces concentrations of the order of 45 to 80 mg. per 100 ml. in one and a half hours, which is well below the threshold. We have not attempted in our experiments, nor do we think it possible, to differentiate between anything more than the very broad stages of drunkenness, and in our opinion it is undesirable to classify intoxication any more precisely.

Moreover, persons charged with being under the influence of drink to a sufficient extent as to render them incapable of having proper control of a vehicle do not fall within the "doubtful" zone at all. In some typical police cases we found the following figures:

Blood alcohol	Percentage of cases
Below 100 mg. per 100 ml.	6
100—150 " "	11
150—200 " "	24
200—250 " "	47
Over 250 " "	12

Of these, those in the group under 100 mg. per 100 ml. were found "Not guilty," so that the fears of the innocent are unfounded in fact. Finally, we must emphasize that the blood-alcohol test does not penalize the guilty, except in so far as it renders the defence more difficult, but it is of enormous value to an innocent person. A person who has had a glass of beer and is charged on the strength of the odour of alcohol in his breath, or whose defect is due to disability or disease, has in the blood-alcohol concentration test a perfect answer to the charge.—We are, etc.,

Metropolitan Police Laboratory, Hendon, Aug. 19.

Treatment of Giant-cell Tumour of Bone

SIR,—If Dr. G. R. Osborn (*Journal*, August 14, p. 351) had been present at the discussion in Belfast he would have heard that there was general agreement upon three points:

1. That a tumour of bone could only be diagnosed with certainty by means of a biopsy.

2. That such a biopsy should consist of a free exploration of the tumour with pathological investigation carried out at leisure and not hurried in the operating theatre, for bone pathology is notoriously difficult, and there are few pathologists qualified to give an opinion in a difficult case.

3. That an osteoclastoma (benign giant-cell tumour) is capable of cure by the simple and safe surgical procedure of curetting.

The importance of these principles is emphasized by the case that Dr. Osborn quotes. This unfortunate man was subjected to *x*-ray treatment without any steps being taken to arrive at an accurate diagnosis. The tumour appeared to enlarge in spite of the treatment. An operation was then performed—a biopsy with immediate frozen sections from which a diagnosis could not be made, so the limb was amputated. Had he fallen into the hands of a surgeon who worked on the lines I have mentioned he would have had an early biopsy and a correct diagnosis, and his limb would have been saved by curetting.

I do not deny that radiation can arrest and cure an osteoclastoma, and there are cases in which inaccessibility or other reason may render this the treatment of choice. But why should the simple and safe surgical method which has been in use for forty years be abandoned for the much more dangerous method of radiation?

Those who advocate the use of radiation in the treatment of non-malignant tumours forget, perhaps, that they are using a method which must have an effect upon the other cellular elements besides those of the tumour. Skin, muscle, vessels, nerves, joint capsule, etc., must all be affected by the radiation, and the osteoclastoma requires, I believe, a heavy dosage. There is a real risk of interfering with function and, in a young person, with growth. A case which came under my observation at St. Bartholomew's Hospital some years ago emphasizes this point.

A young girl, a patient of a surgical colleague, had a tumour of the sacrum, which was diagnosed by biopsy as a benign giant-cell tumour. It was not considered practicable to open up thoroughly and curette, so radiation treatment was given and the growth arrested. But some years later she came to the orthopaedic department because of trouble first in one and later in the other hip-joint. It was then found that her sexual development had failed completely, no doubt because of the effect of the radiation treatment upon the pelvic organs; and she had a progressive slipping of the epiphysis of the head of the femur in each hip (adolescent coxa vara) with progressive arthritic changes such as are practically unknown in this deformity until much later in life. There is strong reason to believe that the development of the coxa vara and the subsequent degenerative changes in the hip-joints were also the result of the radiation treatment.

Dr. Osborn also suggested that the combination of radiation with biopsy is apt to render the tumour malignant. It is difficult to understand his reason for this. If a biopsy has not been done in the first place, there is nothing to prove that the tumour was not malignant from the start. Does Dr. Osborn suggest that merely cutting into an innocent tumour can render it malignant? If not, then the treatment by radiation is the only possible factor that can produce malignancy—surely another reason

against use of this method of treatment for an innocent tumour. I think that most surgeons will prefer to keep to the knife.—I am, etc.,

London, W.1, Aug. 19. R. C. ELMSLIE, M.S., F.R.C.S.

The Vocal Cords in Singers and Speakers

SIR,—One had hoped, in reading the report of the recent discussion on this subject, to have heard something, as Mr. R. R. Woods suggested, of the abnormalities of the larynx as seen by the stroboscope. Those who have witnessed the demonstrations of Stern in Vienna of this method—which is essentially suitable for the investigation of the larynx of the vocalist—will have been surprised to observe in a larynx apparently normal to ordinary indirect laryngoscopy one cord, for example, limping slowly along whilst the other moved normally.

It would be of interest to hear Sir Milsom Rees's experiences with the method in his unique field.—I am, etc.,

Manchester, Aug. 15. W. BRYCE MCKELVIE.

SIR,—All interested in the subject of singing and the care of voices of singers will welcome the further contribution by Sir Milsom Rees in your issue of August 7 (p. 292). The unique experience which Sir Milsom Rees has had through his long association with Covent Garden and the opportunities which he has had of observing the vocal habits of primitive tribes give him the right to speak with an authority which may be claimed by few others. Yet one feels that his statement that there is no such thing as a natural singing voice cannot be accepted unreservedly.

The larynx is primarily a sphincter mechanism guarding the lungs against the invasion of foreign material, and, secondly, it is a mechanism to maintain intrapulmonary pressure, fixing the thorax and helping to stabilize the pectoral girdle during violent movements of the upper extremity. The use of the laryngeal mechanism for the production of purposive sound is a much later adaptation, and has subsequently given rise to both speaking and singing. Anyone who is interested in this subject should read that excellent work by Negus, *The Mechanism of the Larynx*. The act of speaking or singing involves a highly specialized nervous and intellectual mechanism, and one cannot ignore the place which the intellect holds in both these arts. A child learns to speak by hearing the speech of others around it, and it is my belief that people learn to sing for the same reason. The sound pattern in singing is more difficult to imitate than the sound pattern in speech, as singing depends upon the appreciation and imitation of both pitch and tone. That there is a marked difference between the singing of primitive tribes and of cultured races does not cause a great deal of surprise, because the standard of development and the size of vocabulary of the primitive tribe is poor in comparison with the power of speech and the vocabulary of the cultured races. I believe that it is a fact that some of the pigmy races have such a limited vocabulary that they cannot communicate in the dark, as they are then unable to supplement their lack of articulate speech by a language of signs.

If there should be this difference in such an important and necessary function as speech between the savage and the cultured races it is not remarkable that a luxury art, such as singing, should remain undeveloped in primitive people. The increase in the range and quality of the singing voice in the civilized races must, I think, be due to the wider range of instrumental music, which serves as a pattern for the voice to imitate. Sir Milsom Rees points out that the savage tribes sing to the accompaniment of the tom-tom. I wonder whether this is the only sound pattern which the natives have to copy? I suppose that one can take it for granted that the actual anatomical mechanism is present in the less civilized races just as it is presumably present in the higher apes, and the essence of the problem is whether there is a faculty lying dormant which can readily develop under the influence of a suitable musical environment.

I am prepared to agree that nobody sings instinctively; but nobody speaks instinctively. It would be very unusual for anybody to attain the highest level of artistic attainment in any branch of the arts without some training, and I think the difference between training which is directed towards the acquirement of a specialized technique in any art should be clearly differentiated from the training which is primarily directed to the development of a natural aptitude for that art. It is the natural aptitude, which in singing is probably nothing more than a highly developed gift of mimicry, which makes a natural singer.

Granted that the vocal mechanism is a universal endowment, the most important difference between singers and non-singers lies in the brain and not in the larynx. One must agree with Sir Milsom Rees that probably the best singers are yet to be heard, but it seems to me that progress in this direction must inevitably be slow unless the essential problems of voice production are tackled by the combined efforts of the laryngologist and the teacher of singing—a point which I stressed in my paper at the Annual Meeting in Belfast. It surprises me not that vocal disabilities exist so frequently in professional singers and speakers, but rather that the vocal mechanism survives so well, in view of the many different methods of teaching which exist and the rather chaotic state of the subject at the moment. I wonder, too, how such apparently frail structures as the vocal cords survive the exacting demands made upon them in some of the heavier operatic works.—I am, etc.,

Manchester, Aug. 16. VICTOR LAMBERT.

Anaesthesia in General Practice

SIR,—Dr. H. Garner-Evans (*Journal*, August 14, p. 355) is to be congratulated on his happy experiences with pernocton, but it must be remembered, as indeed he himself suggests, that the defects of an anaesthetic may not be revealed until a really large number of trials have been made. Large numbers of administrations of pernocton have been carried out, chiefly on the Continent, and the record of them proves that although there is no question of its efficiency there is considerable doubt as to its safety when compared with the other commonly used barbiturates.—I am, etc.,

London, W.1, Aug. 18. J. BLOMFIELD.

Elongation and Dilatation of the Colon

SIR,—I have read the report of Professor J. R. Learmonth's "last word" on elongation and dilatation of the colon with great interest (*Journal*, July 24, p. 154). With due respect to his position in my alma mater at Aberdeen, I venture to point out that elongation and dilatation are usually only part of a late picture, found so frequently in patients who suffer from disabilities which, judging from the results of treatment, must be ascribed to faulty colonic function. This faultiness is most usually due to developmental abnormalities affecting the colon mechanically, and apparently producing elongation as well as dilata-

tion, which tend to disappear when the mechanical disabilities are adequately treated. In a few of my cases I have had opportunity to establish the fact of such reduction by direct inspection.

The degree of certainty with which one can relieve distressing symptoms (both intra- and extra-abdominal) in cases of colonic insufficiency which is not due to ordinary organic disease, and which react unsatisfactorily to medical therapy, is astonishing. It convinces me that these very common developmental abnormalities are the most important factors in the production of such symptoms. In particular, the evacuation of the colon attained is usually so satisfactory that patients speak of the act with enthusiasm!

I am fully aware of the hostile attitude towards surgical treatment of these conditions prevalent in the British Isles and elsewhere. Sir William Arbuthnot Lane, by advocating treatment which in many cases could only be described as disastrous, "queered the pitch" which he had so carefully prepared. The inadequate measures put forward by others, planned to relieve only parts of the trouble, met with the discouraging degree of failure which one would nowadays expect. In spite of all that the results of the treatment which I advocate (gradually evolved over a period of twenty-five to thirty years) make me wish that some other surgeons would fairly put it to the test. There is indeed ample material available. For that reason I have described the operation very fully in my book *The Colon as a Health Regulator* (Macmillan Company of Canada, Toronto—represented by Macmillan and Co., Ltd., London), which was reviewed in the *Journal* of June 19 (p. 1259).

My book is concerned chiefly with the recording of actual facts. The facts in relation to the results of treatment are so encouraging, and in some cases so surprising, that I am hopeful that those who are interested in the subject will read my book before they accept Professor Learmonth's dogmatic condemnation of surgical intervention when faulty colonic function has to be treated. I am convinced as to the efficacy of proper surgical treatment in these colonic cases. The propriety of the treatment is evidenced by the relief which it affords in the matter of local symptoms (both subjective and objective) and in giving a feeling of general well-being previously absent. One can speak, just as Professor Learmonth does, of "dramatic immediate improvement in function," and very few patients fail to maintain that improvement.

Armchair criticism is to be deprecated in the discussion of this matter, as it is in other practical problems. The fact is that very few can speak with justifiable conviction about the full surgical treatment I recommend because they have not tried it! Most of my patients have undergone careful and prolonged medical treatment by various doctors without relief. A recent very miserable one brought to me a dossier of prescriptions, diet sheets, regulations for daily life, etc., more than an inch thick. He had consulted twenty-two doctors, and had been to a special clinic in Paris—without any benefit. Yet within ten days of operation his outlook on life had become completely changed and has remained so. His remarks are exuberant with regard to his general health and the action of his colon! A similarly affected patient, operated on seven years ago, has been seen unexpectedly, owing to an injury, since I decided to write this letter. His enthusiasm concerning my treatment of his abnormal colonic conditions has not lessened, so that the effect of the operation need not be ephemeral, as some destructive critics would have it!—I am, etc.,

Montreal, Aug. 11. HENRY M. W. GRAY.

SIR,—In a note on *The Colon as a Health Regulator* by Sir Henry M. W. Gray (*Journal*, June 19, p. 1259), it is said that one statistical statement "does not accord" with another statistical statement. The first statement refers to the number of deaths—namely, four—in the series of 205 operations, while the second refers to the number of cases in which complete failure has to be recorded—namely, 1 per cent. in the series. As these figures deal with two entirely different computations the question of "accord" does not arise: on the other hand, there is no contrariety between them. The last sentence, "Other claims unsupported by figures may be even wider of the mark," can have no bearing whatever, as your reviewer up to this point has failed to prove anything wide of the mark.

The impression is inescapable that your reviewer indulges in fault-finding in questioning the data of the book, with the evident intention of disparaging this work, but those who know the character and reputation of the author will give no credence to such misleading statements. The really unfortunate result of such "notes," appearing as they do in a publication of the high standing of the *British Medical Journal*, is that they may turn medical men away from a study of the book and thereby, I am convinced, deprive many patients of the often very great and permanent relief that only the treatment outlined in this book can afford. Having had the opportunity of examining numerous patients submitted to the author's operation, I can assure your readers that Sir Henry is distinctly conservative as to the beneficial results attained. —I am, etc.,

W. M. MACNAB, M.B.

Victoria, British Columbia, Aug. 1.

SIR,—In reply to Mr. E. G. Slesinger's letter (*Journal*, August 14, p. 352), we must express our regret at having inadvertently misrepresented his views on the surgical problems of the elongated pelvic colon. In extenuation we can only say that we were misled by the very words which he quotes from his original paper: "The following remarks are therefore not intended to suggest that elongation of the pelvic colon necessarily results in the production of symptoms, but rather to point out that in certain cases such elongation produces results sufficiently severe to call for relief. . . ."

These remarks seemed to us to indicate that Mr. Slesinger believed that certain cases of uncomplicated dolichosigmoid were capable of producing symptoms requiring surgical treatment. While we are in complete agreement with many of Mr. Slesinger's published views, there is, nevertheless, a considerable divergence in our respective attitudes to some aspects of the subject; the chief difference is that we do not believe that dolichosigmoid in the absence of certain complicating factors can ever require surgical intervention.

Our opinion still coincides with that of Mr. Garnett Wright (*Journal*, April 28, 1928, p. 712), that the production of bands on the outer surface of the mesentery is due to plastic peritonitis set up by repeated attacks of partial strangulation, and not to a natural reaction of the body to the strain of an overloaded sigmoid colon. The cases referred to by Mr. Slesinger in his letter to the *Journal* of July 15, 1933 (p. 129), in which a peculiar type of constipation was produced by a prolapse of the loaded pelvic colon and consequent abnormal angulation at the pelvirectal junction, do not appear to us to require surgical intervention. Our own standpoint is that radical surgical measures should be reserved for patients in whom the clinical and radiological features present a characteristic

syndrome, as summarized by us in our letter to the *Journal* of August 7 (p. 293), and that such cases are by no means rare.—We are, etc.,

D. LIGAT.
St. Leonards-on-Sea, Aug. 18. T. D. OVEREND.

Insects and Disease

SIR,—I have read with interest Major-General W. P. McArthur's lecture (*Supplement*, August 14, p. 126), in which he states that the fever which afflicted Cromwell's troops in Ireland was typhus fever. I give you the true facts, leaving your readers to judge whether the disease was typhus fever or imported plague. On January 30, 1649, King Charles I was executed. In July of that year an English ship arrived in Galway with uniforms and supplies for the few hundred Royalist soldiers of Ormond's army quartered there. This vessel was said to carry in those supplies "the contagious infection of the plague in its first appearance in Ireland. . . . Plague broke out immediately." The *Annals of Galway City* (Historical Manuscript Commission, Tenth Report, Appendix, Part V, p. 500, London, Eyre and Spottiswoode, 1885) gives the following:

"That this Toune of Galway, the last year being the mayoralty tyme of Sir Walter Blake, Knight, was visited with the contagious infection of the Plague which continued from July one thousand six hundred and fortie nine till spring after."

"That all members of the toune have met in the country and have consented to a tax of two thousand marckes sterling towardes the charges of physitians and providing of all other necessaries requisit for the purifing and clensing of the said toune which was with all earnestness pursued by these intrusted with that charge."

The city once freed from infection, the inhabitants returned; Galway had lost 3,900, Dublin 30,000, from the plague. But despite all these sanitary methods, Galway City experienced later a second visitation. Colonel Lawrence, an officer of Cromwell's army, in his *Interest of Ireland* (Part II, pp. 86–7) writes:

"Plague and famine had so swept away whole counties, that a man might travel twenty or thirty miles and not see a living creature, man, beast, or bird; our soldiers would tell stories of the place where they saw a smoker, it was so rare to see either smoke by day or fire or candle by night."

Lawrence estimated that five-sixths of the Irish population had perished, an estimate adopted by Prendergast in his *Cromwellian Settlement of Ireland* (1863). The plague ran its course until 1653. Twelve years later, in 1665, it raged in London. General Ireton died of plague in Ireland. One would not expect that he would suffer from louse infection (typhus), and beasts and birds do not die of typhus fever or of "Buchan's malaria." Yet Galway City for nine months successfully resisted the Cromwellian siege, a proof of its powers of resistance, even with the loss of its best fighting men in two visitations of the plague.—I am, etc.,

Athenry, Co. Galway, Aug. 16. C. H. FOLEY.

Injection of Umbilical Vein in Retained Placenta

SIR,—Mr. David Currie, in his paper in the *Journal* of July 10 (p. 58), once more emphasizes the dangers of manual removal of the placenta—45.2 per cent. morbidity and 15.4 per cent. mortality are indeed staggering figures. Since the publication of his first paper (1932), in which he pleaded for a more extended use of cord injection, I have been employing this method with certain modifications for the treatment of retained placenta. Starting at St. Mary's Hospital, London, in that year, I have continued to use this form of treatment in the obstetric unit of Hong Kong University.

The technique is even simpler than that advocated by Mr. Currie, and has been reported elsewhere (1936). All that is required is a 200 c.cm. metal ear syringe. This is filled with warm sterile saline or water. The cord is re-cut and the nozzle of the syringe is pushed into the umbilical vein. One can tell if the nozzle is inserted in the vein, for when it is in this vessel it can be easily pushed down the cord. The nozzle being held firmly in the cord with the left hand, the contents of the syringe are rapidly injected. An assistant refills the syringe and a further 200 c.cm. are quickly introduced. Following this, Credé's manœuvre is attempted. In one case 800 c.cm. were injected without any deleterious effect before the placenta was expressed. One of the causes of failure of this treatment is the presence of a contraction ring.

The method as outlined above is so simple that even a midwife can undertake it. There are occasions when medical aid is not at hand and a midwife has to deal promptly with a major emergency. Rather than wait till the doctor's arrival and severe exsanguination of the patient, the midwife could at least try cord injection before putting her hand in the uterus to remove a retained placenta. In the Tropics manual removal of the placenta is even more hazardous than in England, for many of the patients who come to hospitals for their deliveries are suffering from a marked degree of secondary anaemia, malnutrition, infections, etc.

Lack of conservatism in obstetric practice is now recognized as a contributory factor in the high maternal mortality which is found in certain countries. Mr. Currie is to be commended for reviving a conservative method of treatment which has been allowed to remain in desuetude for a century.—I am, etc.,

Hong Kong, Aug. 6. W. C. W. NIXON.

Tennis Elbow

SIR,—In the past the term tennis elbow was used in rather a vague sense, and many authorities included under it a heterogeneous collection of disabilities in the region of the elbow-joint and forearm. In order that the results of treatment may be of more comparative value it is necessary to have a standard definition of the term. Tennis elbow must, in virtue of its name, stand for the commonest cause of disability in the elbow of a tennis player.

According to Mr. G. P. Mills (*Journal*, July 31, p. 212) the commonest condition in his series of fifty-eight cases was one characterized by radio-humeral tenderness, presumed to be due to the nipping of the frayed edge of the coronary ligament. He does not mention what proportion of the cases were tennis players, however. In my own experience another condition is responsible for the majority of cases of tennis elbow, and is best designated as traumatic periostitis at the origin of the extensor carpi radialis brevis muscle. Both conditions may occur, and often do occur, in people other than tennis players. Mr. Cyriax, in the *Journal of Bone and Joint Surgery* (October, 1936) points out no fewer than twenty-six pathological conditions that have been described as responsible by various authors, all of which goes to show that tennis elbow is an incredibly bad term. Nevertheless, in order

to establish that traumatic periostitis of the extensor carpi radialis brevis is the responsible condition, may I give a brief description of its principal features.

1. It is in my experience the commonest of the disabilities occurring in the elbow of a tennis player.

2. It is brought on by the excessive use of the extensor carpi radialis brevis muscle, as in the fixation of the wrist in slight dorsiflexion to obtain the maximum grip on the racket.

3. It is localized to the site of origin of the muscle.

4. The pathology as shown by operative exploration is best described in stages. First, there is a tear at the site of origin of the tendon from the periosteum, with extravasation of fluid forming a localized oedema; the effusion of blood is slight owing to the relative avascularity of the tendon; secondly, the oedema or clot is organized, and forms a fibrous tissue adhesion. If the condition is extensive it may give rise to such a marked periosteal reaction that it will show in an x-ray film.

The localization of the site of the disability is dependent on the following factors:

(*a*) The pain occurs on increasing the tension in the extensor carpi radialis brevis muscle—for example, by active contractions as in lifting or gripping with the forearm pronated, or by passive stretching as in flexion of the wrist with the elbow extended. Mr. Cyriax points out a useful test: "Active extension of the wrist by a patient with tennis elbow causes him more pain when it is resisted by pressure on the heads of the metacarpals than when the pressure is applied on the tips of the extended fingers."

(*b*) The pain occurs at the site of origin of the extensor carpi radialis brevis muscle, and may in some cases be accompanied by pain in the line of the muscle itself.

(*c*) Tenderness is maximal at the origin of the extensor carpi radialis brevis muscle—that is, just *above* the capitellum on the anterior aspect of the humerus, and not strictly localized to the radio-humeral joint line or the epicondyle itself.

The results of treatment indirectly confirm the pathology, and treatment itself naturally depends on the pathological stage of the condition. In the acute stage rest from tennis is the main line to be adopted; occasionally manipulation dispersing the localized oedema will relieve the tension and so abolish the pain. In the second stage, the stage of adhesions, manipulation may rupture these tender structures and effect a cure. Lastly, open operation, whereby the periosteum is elevated from the bone in the affected region, can undoubtedly be successful in a still larger proportion of cases.

It is for reasons contained in the above description that I think the term traumatic periostitis should be accepted as synonymous with tennis elbow, and other cases, such as nipping of the frayed edge of a coronary ligament, ligamentous strain, bursa formation, arthritis of the elbow-joint, generalized fibrositis, or any of the other twenty-six pathologies which have been suggested, should be diagnosed under their appropriate headings.—I am, etc.,

Norwich, Aug. 10. G. K. McKee.

Malaria Control

Sir,—In the *Journal* of June 5 (p. 1175) there appeared a letter by Dr. W. M. McDonald on the use of quinine. If the figures given are correct, then each person would have had, on an average, a dose of 140 grains. At a daily dose of 5 grains that would be sufficient for thirty days and no more. But some of that quinine was used for curative purposes in large doses, so that the average of 5-grain prophylactic doses must have been taken for less than thirty days. It is obvious then that the quinine was not used properly as a prophylactic; the population could not possibly have had the daily dose of 5 grains over the necessary period of months.

This problem of quinine is very old, and also tiresome. From an extensive experience in such areas I am convinced that quinine is a most valuable prophylactic; and one wonders why there is so much doubt about. The figures given in this letter afford a perfect explanation. They seem to me to be a terrible admission of the failure of the *measures*, but scarcely concern the method, as the method was not followed. That is exactly what one finds in these malarial areas; where the people take their daily dose regularly and at the proper time they do not get malaria, or very seldom. It is the people who pretend to take it regularly but who certainly do not do so who go down; then they take very large doses and become seriously ill.

I suggest that Dr. McDonald's letter shows conclusively that it is the administration which is at fault and not the method. I consider that the agitation against the use of quinine as a prophylactic does a vast amount of harm. No one will decry the other measures, such as drainage, etc., but it is not often easy to apply them; whereas the quinine can be used everywhere and by everyone, with few exceptions.—I am, etc.,

Surrey, Aug. 15. W. F. Cooper.

P.S.—Actually, I am about to leave for a district where everyone is troubled with mosquitos, where malaria is quite bad. I do not even have nets. But then everything is drained, and if one fly or mosquito is found the boys have to turn out and hunt the source. So that it may be seen that I adopt every other means, as well as quinine, to live in comfort and health. It is when one goes about that one requires and finds the benefit of quinine.

Squint and Heterophoria

Sir,—In the discussion on squint and heterophoria in the Section of Ophthalmology at the Annual Meeting I was reported to have pointed out "the dangers involved in too radical operative disturbance of the extra-ocular muscles" (*Journal*, August 7, p. 285). It was what I think is a mechanically incorrect, and not a radical correction, to which I object. I consider that in squint the place of insertion of the muscles into the eyeball is not at fault; that advancement or recession operations cannot result in harmonious action of the recti and oblique muscles; and that the right operative procedure to correct the deformity is to lengthen a muscle that is too short by longitudinally splitting it into three strands and tenotomizing the two outer strands (lower and upper), and to shorten a muscle that is too long by dividing the tendon the necessary distance back from the eyeball and suturing tendon to tendon.—I am, etc.,

Londonderry, Aug. 19. J. W. Killen.

Spa Treatment in Hot Weather

Sir,—Professor A. J. Clark's paper on individual variation in response to drugs (*Journal*, August 14, p. 307) has inspired the following notes.

Dealing with spa waters as an external application the ratio of dose to body weight is negligible, but amongst other factors affecting response is the state of the weather at the time of treatment. I had a good opportunity of observing the reactions of twenty-one patients during the period of hot weather from July 30 to August 14. The cases included eight of osteo-arthritis, five of gout, four of muscular rheumatism and fibrositis, two of fibrositis and neuritis, and two of colitis.

All the gouty cases did well, and all but one were able to stand full treatment, most of them having immersion baths and

vapour baths on alternate days. Three of the osteo-arthritic group had to have their treatment times and the temperature of the water and packs reduced considerably, and even then complained of feeling unduly tired, with an increase of pain in the joints. They were all of similar age and condition. The remaining five cases of osteo-arthritis stated that they liked the hot weather. The muscular rheumatism group also stood the treatment well, but two cases of sciatica (fibrositic type) were quite content to be immersed in water at 98° F., and have treatment on alternate days only. The weather made no difference to the cases of colitis.

The blood pressure and pulse rate were taken before and after treatment, and were found, as usual, to come down where high and go up a little where low. The general feeling of well-being, with increased appetite, was apparent in all except the three osteo-arthritics, who still felt fatigued on reduced treatment. Though the cases are taken haphazard as they came to me, there was no obvious reason for this—for example, dental or other sepsis or other disease—in these three patients. One of them comes regularly in the colder months for osteo-arthritis of both hips, and can then stand full treatment with benefit.

The following two cases of osteo-arthritis and two cases of gout show in the first case of each condition normal reaction to normal treatment, and in the second cases the modifications necessary on account of the warm weather.

Case 1.—Age 64: osteo-arthritis knees, lower lumbar vertebrae, and fingers (Heberden's nodes); blood pressure, 180/100; pulse 76, regular. Treated by mineral water, 20 oz. daily; deep bath at 102° F. with undercurrent douche to back and knees at 110° F. for last half of bath; fifteen-minute bath followed by full pack to waist line for fifteen minutes. Three baths a week on alternate days. Mud packs to back and knees for fifteen minutes; short needle douche at 101° F., followed by thirty minutes' massage to thigh muscles and back. Three treatments a week. After a week's treatment the patient was walking better, with more movement of the lower spine and no pain; blood pressure 160/97; standing treatment well.

Case 2.—Age 68: osteo-arthritis hips and sacro-iliac joints, and slightly in the dorso-lumbar region; blood pressure, 170/100; pulse 66. Treatment was as above. After second treatment complained of feeling sick and tired; gave day's rest, and prescribed electric reclining bath at 100° F. for fifteen minutes, with sponging of forehead during bath and pack, which was only used for hips; three baths a week. No complaint of sickness or undue fatigue, and patient was able to finish course, with general improvement in walking and less stiffness on getting out of chair after sitting.

Case 3.—Age 70: gout; blood pressure, 190/105; pulse 78, regular. Chronic tophi in feet and wrists. Treated by deep-flowing water baths at 102° F. for fifteen minutes, followed by light pack, cold towels to chest, neck, and forehead for fifteen minutes; three treatments a week on alternate days. Vapour baths in cabinet to 110° F. for fifteen minutes. Cold sponging to forehead during bath, and small Leiter's coil to precordium with ordinary tap-water running through, followed by needle douche for three minutes, cooled down to 98° F.; light pack; three a week. After three treatments the blood pressure fell to 170/100, and after ten to 160/100; pulse 70. This patient had our normal treatment and did well.

Case 4.—Age 63: gout; blood pressure, 160/95. Recent acute attack of gout in great toes; first on the right side and then, while still on colchicum, potassium iodide, and much-restricted diet, attacked the left great toe as well. The acuteness had disappeared, but there was still some tenderness remaining ten days after all swelling had disappeared. Deep bath prescribed as above. Patient felt very tired after the bath, and disinclined to get up for dinner that evening. On seeing him the next morning he still complained of feeling tired. Prescribed a day's rest and a vapour bath next day, which I superintended at 11 a.m. Blood pressure before treatment was 150/90; pulse 60, regular, and of fair volume. Vapour bath (cabinet), temperature gradually increased to 110° F. in five minutes, kept at this for seven minutes; cold sponging forehead, and Leiter's coil to chest; two minutes' needle douche cooled down to 95° F.; no pack. Rested under cool sheet for fifteen minutes. Directly after bath blood pressure was 150/90; pulse 56. Had an hour in bed and got up for lunch, and went for a drive in the afternoon. Next morning he said he felt well; continued this mild vapour bath daily, except Sundays, for nine days. All tenderness had disappeared, was walking well and feeling better in every way.

The number of cases observed were too few to generalize on, but the personal factor was well brought out. I rather think that the patients who could stand full treatment in hot weather got quicker benefit than they would have done in cold weather.—I am, etc.,

Bath, Aug. 18. A. GORDON WATSON.

Insulin Hypoglycaemia

SIR,—In view of the letter from Dr. H. S. Pemberton in your issue of July 24, may I be allowed to draw attention to an abstract in the Epitome (*Journal*, June 19, No. 490, p. 98) of a paper by R. Freudenberg. His subject is the administration of insulin shock therapy for schizophrenia. He

"draws attention to the parallel between vitamin B_1 deficiency and insulin shock. Experimentally it has been shown that in both conditions there is a lessened intake of oxygen in the grey matter of the brain. . . . Freudenberg has found that the administration of vitamins B_1 and B_2 and adrenal cortex hormone has succeeded in interrupting coma in non-reversible cases of insulin shock. . . . The author claims that the administration of vitamins B_1 and B_2 is a valuable therapeutic agent in making insulin shock therapy safe."

No information is given as to whether the obvious extension of this experiment to diabetes has been tried, but it seems that vitamin B might possibly prove of use in such cases as those mentioned by Dr. Pemberton, and even more so in cases treated by protamine zinc insulin, where delayed overaction of the insulin is so hard to counteract.—I am, etc.,

Bathford, Aug. 9. A. G.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

John Hart-Mercer, M.B., Ch.B.Ed. has been elected to the Gwynaeth Pretty Studentship for three years from October 1, and he has been awarded the Nita King Scholarship for the same period.

At a congregation held on July 30 the following medical degrees were conferred:

M.D.—*J. D. Procter, W. B. A. Lewis.

M.B., B.CHIR.—*E. M. Evans, *P. Kidd, *C. R. Morison, *G. O. Richardson, *G. M. Fleming, *C. D. Anderson, *H. A. Brook, *T. P. H. McKelvey, *E. F. Aubert, *I. A. Guest, *P. F. Barwood, *J. O. Collin, *W. H. Ekin, *M. T. Parker, *E. A. Pask, J. F. H. Bulman, R. C. B. Barbor, F. S. Cosh, E. B. French, H. Haigh, J. P. Reidy, W. B. Waterfall, R. C. S. Dick, C. J. S. Sergel, R. W. Watts, J. P. Singer, C. T. A. Burgess, J. N. Fell, J. C. Gilson, E. A. G. Goldie, C. E. D. H. Goodhart, J. N. Horne, R. W. Markham, J. H. Moir, A. K. Pardhy, K. M. M. Sheldon, H. R. Wynne, L. G. Braddon, A. C. Cunliffe, W. G. Murray-Browne, R. C. Neville, M. Feiwel, C. M. Dickins, T. P. Myles, C. G. Scorer, P. H. Willcox, R. F. Ashwin, R. Edwards, N. F. Coghill.

* By proxy.

During the month of July the titles of the degrees of M.B., B.Chir. were conferred on M. B. Billington and G. M. S. Caldwell of Newnham College, and that of M.B. on E. M. Wright of Girton College.

POSTGRADUATE COURSES FOR INSURANCE PRACTITIONERS*

The following are particulars of postgraduate courses for insurance practitioners at the British Postgraduate Medical School, Hammersmith, London. These courses have been arranged jointly by the Insurance Acts Committee and the Ministry of Health. Those practitioners wishing to participate should apply at once to the secretary of their local panel committee for a form of application.

SEPTEMBER COURSE

This course will begin on Monday, September 20, and end on Saturday, October 2. The subjects are as follows: principles of the examination of patients; pain in the foot; common types of anaemia, diagnosis and treatment; ante-natal examination; common skin diseases; pneumonia; nephritis; enlarged prostate and cystitis; common diseases of ear, nose, and throat; diagnosis of nervous diseases; eye conditions in general practice; allergic diseases; chronic rheumatism; children's diseases in general practice; abdominal pain; infectious diseases; demonstration of local anaesthesia; surgery of the chest; migraine and headache; toxaemias of pregnancy; psychiatry in general practice.

The lecturers include: Professor Thomas Beattie, Mr. Robert Milne, Dr. Janet M. Vaughan, Professor James Young, Dr. R. T. Brain, Dr. J. L. Livingstone, Dr. Horace Evans, Mr. Terence Millin, Dr. George Bray, Dr. Charles W. Buckley, Mr. V. Zachary Cope, Dr. J. S. Anderson, Mr. John Hunter, Dr. Macdonald Critchley, Professor F. J. Browne, and Dr. Henry Yellowlees.

OCTOBER COURSE

This course will begin on Monday, October 18, and end on Saturday, October 30. The subjects are as follows: principles of the examination of patients; ante-natal examination; rheumatoid arthritis; possibilities and limitations of radiotherapy; demonstration of local anaesthesia; common types of anaemia, diagnosis and treatment; convulsions and similar conditions; frequency of micturition; diagnosis of nervous diseases; common diseases of throat, nose and ear; psychology in general practice; common skin diseases; obstetric injuries, immediate and remote effects; acute pyogenic infections, including those of the hand; pulmonary tuberculosis; children's diseases in general practice; toxaemias of pregnancy; dyspepsia; cholecystitis; the acute abdomen; eye conditions in general practice.

The lecturers include: Professor F. R. Fraser, Professor James Young, Mr. G. F. Stebbing, Dr. Janet Vaughan, Dr. Macdonald Critchley, Mr. V. W. Dix, Dr. J. R. Rees, Dr. R. T. Brain, Mr. V. B. Green-Armytage, Mr. Charles Donald, Dr. R. C. Winfield, Professor F. J. Browne, Sir Arthur F. Hurst, Dr. Charles Miller, and Mr. H. C. Edwards.

NOVEMBER COURSE

This course will begin on Monday, November 15, and end on Saturday, November 27. The subjects are as follows: principles of the examination of patients; physiotherapy; dyspepsia; pyuria; asthma; common types of anaemia, diagnosis and treatment; injuries and infections of the hand and wrist; endocrine disturbances in gynaecology; diagnosis of nervous diseases; common diseases of throat, nose, and ear; convulsions and fits; heart failure; haemorrhoids and varicose veins; difficult labour; streptococcal infections and recent therapy; common skin diseases; infectious diseases; acute abdominal emergencies; common respiratory diseases; children's diseases in general practice; eye conditions in general practice.

The lecturers include: Professor G. Grey Turner, Dr. A. E. Clark-Kennedy, Mr. J. Swift Joly, Dr. G. W. Bray, Dr. Janet Vaughan, Mr. J. P. Hosford, Dr. P. M. F. Bishop, Dr. J. Purdon Martin, Dr. Paul Wood, Mr. C. Naunton Morgan, Mr. Leslie Williams, Dr. Leonard Colebrook, Dr. R. T. Brain, Dr. W. Gunn, Mr. Philip Turner, and Dr. W. E. Lloyd.

* Details of grants payable by the Ministry of Health to insurance practitioners who wish to take these postgraduate courses will be found in this week's *Supplement* at page 153.

Medical News

The annual dinner of Westminster Hospital Old Students will be held at the Park Lane Hotel, London, on Saturday, October 2, with Mr. A. F. MacCallan in the chair. The inaugural address of the school will be given at the Caxton Hall, London, on Monday, October 4, at 3 p.m., by Sir Seymour Hicks.

An anonymous donor has offered the Royal Northern Hospital, Holloway, London, a gift of £40,000 provided that a similar amount is contributed by others interested in the work of London's seventh largest general hospital. This munificent gift is made in connexion with the special appeal for £350,000 for the reopening of wards and for the renovation and rebuilding of certain parts of the hospital.

The ninth annual conference of the National Smoke Abatement Society will be held at the Philosphical Hall, Leeds, on Thursday, Friday, and Saturday, September 30, October 1 and 2. The programme includes discussions on town planning and smoke abatement and education and smoke abatement, and papers will be read by representatives of the regional committees. Full particulars can be obtained from the secretary of the society, Chandos House, 64, Buckingham Gate, Westminster, S.W.1.

The fifth session of the Australasian Medical Congress was opened by Sir George Murray, the Lieutenant-Governor, at Adelaide on August 23. Four hundred and fifty medical delegates from all parts of Australia and New Zealand are attending the Congress. Oversea representatives include Professor Grey Turner from England and Dr. C. E. G. Beveridge from the Sudan. The congress is meeting for six days under the presidency of Sir Henry Newland. On the afternoon of August 23 the Chief Secretary, Sir George Ritchie, laid the foundation stone of the Institute of Medical Research, to which Dr. E. W. Hurst has been appointed director.

The tenth Congress of French-speaking Gynaecologists and Obstetricians will be held in Paris from September 30 to October 2, under the presidency of Professor Mocquot.

We learn from the *Pharmaceutical Journal* that new regulations imposed by the National Health Administration of China prohibit in all advertisements, circulars, labels, or wrappers of patent medicines any wording or meaning suggestive of the futility of professional medical treatment, or any contemptuous or detrimental remark about the medical profession.

Dr. H. M. O. Lester, Deputy Director of Sleeping Sickness Service, Nigeria, has been awarded a Carnegie grant for visits to the Congo, Tanganyika, the Southern Sudan, and other parts of Africa to study methods of sleeping-sickness control.

The King has granted Dr. Robert Scott Taylor authority to wear the Insignia of the Third Class of the Brilliant Star of Zanzibar conferred upon him by the Sultan of Zanzibar in recognition of valuable services rendered by him.

Dr. Jean Charcot, drowned when the *Pourquoi Pas?* foundered off the coast of Iceland, has been succeeded by Dr. Louis Martin, director of the Pasteur Institute, as a member of the French Academy of Sciences. Dr. Charcot is succeeded in the French Academy of Medicine by the author Dr. George Duhamel.

The Egyptian Medical Institute of Cairo, which is the oldest and largest European institute in Egypt, has elected as its president Professor Mecchi, director of the Italian Hospital and head of the Royal Society of Medicine at Cairo.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*
SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh;* telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin;* telephone 62550 Dublin).

QUERIES AND ANSWERS

Ultra-violet Irradiation

"ULTRA-VIOLET" writes: I would be much obliged for information as to the present position of ultra-violet medication for people who are in tolerably normal health, but who for one reason or another are run down, overworked, etc. Is it likely to be of any assistance to them, and is there any objection to its frequent use over a period of years?

Vaccine Reactions

Dr. C. M. HEANLEY (Hassocks, Sussex), in reply to "Rural G.P." (*Journal*, August 14, p. 358), writes: What is meant by "persistently overdosed"? After experiments in South Africa doses of 6,000 to 7,000 millions of pneumococci at seven-day intervals were recommended as a suitable prophylactic. The trouble may be due to other organisms, perhaps in a blocked maxillary, frontal, or ethmoidal sinus, and not to the vaccine.

Cancrum Oris

Mr. G. H. PEAKE (Guildford), in reply to Dr. Hope Trant (*Journal*, July 3, p. 48), writes: I saw many cases of cancrum oris among the natives of Madagascar, and treated them by burning the base of the ulcerated surface very thoroughly with fuming nitric acid. My first case was that of a child aged 2. The sore, which began on the inside of the upper lip (left side), had perforated right through it; it did not appear to be painful, as the child was suckling well. There was a sanious and stinking discharge. Under light anaesthesia the wound was thoroughly cauterized with pure nitric acid. Four days later this was repeated, as the sore had spread. Five days after that a large piece of the superior maxilla came away with several teeth. The cavity was again thoroughly burnt. The wound was washed several times daily with lotio hydrarg. perchlor., 1 in 4,000, and stimulants were given. Three days later the wound had much improved and there was no sign of any further spread, but a new focus had started on the inner side of the right upper lip. The whole was cauterized again. This application checked the disease and the sore healed rapidly. Though the hole in the lip (and upper jaw) had been very extensive, the lip contracted and almost closed, leaving very little deformity. Out of seven subsequent cases treated in the same way one patient died. In this case the condition started in the left ear and the child died of exhaustion with cerebral symptoms.

LETTERS, NOTES, ETC.

Dangers of Glass Ampoules

Lieut.-Colonel H. H. KING, C.I.E., I.M.S. (ret.), writes: While in charge of a laboratory in India I noticed that when ampoules in which a vacuum had been created were filled with vaccine the inrush of vaccine carried in small particles of glass from the breakage of the stem. On examination of the deposit from several ampoules many of the glass particles were found to be minute enough to pass through an ordinary small hypodermic needle, and they could thus be injected into a patient along with the vaccine. If there are any manufacturing or other laboratories using this method of filling ampoules they should know of this danger. I notice that some firms are putting out ampoules containing two solutions separated by a glass partition that has to be broken before the two substances are mixed. Has the possibility of the dissemination of small splinters of glass in these ampoules at the time of breakage been examined?

An Unusual Treatment

"BEN TROVATO, M.D.," writes: In an entertaining book of naval reminiscences entitled *My Mis-spent Youth*, I came across the following passage: "One of the younger midshipmen who had a rather high-pitched voice, was observed not to be developing properly. A special drill was invented. He was stood on the end of the gun-room table, facing outwards and quite stiff, and then his feet were knocked forward. He fell three or four feet with a jarring thud. A few weeks of this treatment had the desired effect." I should like to know whether this inexpensive but slightly barbaric treatment of the undescended testicle is one more proof of the resourcefulness of the Royal Navy, or whether it is traditionally practised by other communities to whom gonadropic hormones are not available.

Holidays for Factory Girls

We have received the following appeal, signed by the Countess of Sandwich, Miss Lilian Braithwaite, Miss May Wynne, Mrs. Mary M. Paget, the Bishop of London, the Chief Rabbi, and Lady Loch, on behalf of the Factory Girls' Holiday Fund. "Will you allow us to make to your readers an urgent appeal for the Factory Girls' Country Holiday Fund? It has helped hundreds of the poorest of London's girls and women to go away for the August Bank Holiday week, the only clear week they could get in the whole year. Many more are hoping to get away during the next weeks; but at present our funds are exhausted. A large number of the girls sent away are hardly more than big growing children, having recently left school for work in factories and warehouses. This summer holiday means even more than a health-giving change of air and surroundings. Boarded with kindly cottagers living in their own well-ordered little houses, the girls and women exchange with country folk experiences which make life fuller and more complete. Those from London gain, too, a new interest in nature—in the cultivation of flowers, and fruit, and vegetables, and in the care of animals. Think what this means to people who live for the rest of the year in crowded dwellings and stuffy streets, often far away from parks and large open spaces! A summer holiday means much to most of us. To them it means a benefit which is almost indescribable. Will your readers help us to save these girls from bitter disappointment? Gifts will be thankfully received and acknowledged by the honorary treasurer, Mrs. Slater, Lowood, Hindhead, Surrey, or by Miss Canney, 75, Lamb's Conduit Street, London, W.C.1."

Corrigenda

In the paragraph on Messrs. Hewlett's preparation of para-aminobenzenesulphonamide at page 217 of the *Journal* of July 31 the name of this product was given as "P.B.A.S." This should have read "P.A.B.S."

Dr. L. G. MILLAR PAGE writes: In my letter on prominal in epilepsy (*Journal*, August 21, p. 393) I said: "Dr. Millman has reported a reduction of one-third in the number of fits in a year under prominal. . . ." This should have read: "Dr. Millman has reported a reduction *to* one-third in the number of fits. . . ." Or, more correctly, to quote Dr. Millman, "The total number of fits under prominal treatment is shown to be approximately one-third of the number during a similar period under luminal therapy."

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

169 Nutrition in Children

W. Kornfeld and E. Nobel (*Wien. klin. Wschr.*, June 25, 1937, p. 959) discuss the value of the modern methods of determining the state of nutrition in children. They come to the conclusion that the simple classification based on body weight and the usual measurements of height are satisfactory when applied to large numbers. In the case of children who require special supervision, however, other additional methods of examination, such as the investigation of the condition of the skeleton, of the muscles, and of the adipose layer are necessary. For the purpose of investigation children of average height and normal weight should be grouped together, those of average height but under weight forming another group, those of excessive or reduced height but of normal weight a third, and so on. These groups should then be investigated in detail and the findings correlated with the social conditions.

170 Iodine Poisoning

W. B. Seymour (*Arch. intern. Med.*, June, 1937, p. 952) reports a fatal case of exfoliative dermatitis due to the application of tincture of iodine to the skin. The patient was a man, aged 52, who was suffering from bilateral pulmonary tuberculosis. Treatment by artificial pneumothorax was instituted. The preparation of the skin consisted in the application of full strength tincture of iodine (*U.S.P.*), followed by the removal of the iodine with 70 per cent. alcohol. The sixth application was followed by a morbilliform eruption over the whole body, which became confluent on the back, but disappeared in three days. Ten days later iodine was again applied. The next day there was a generalized morbilliform eruption and the prepared area was a fiery red. By the sixth day after the last application of iodine the skin was peeling from the body in large sheets, leaving great denuded areas which exuded serum, so that the bed was constantly wet. There was a thick purulent discharge from the eyes and a profuse flow of viscid mucoid saliva from the mouth. Death occurred the same day. At necropsy, the tracheal mucosa was desquamated. The oesophageal mucosa had also desquamated and formed a cast of the lumen. Microscopical examination of the skin showed complete desquamation of the epithelium. In the corium there was a scant, diffuse infiltration of cells, consisting mainly of lymphocytes and polymorphonuclear leucocytes, with an occasional eosinophil cell. The author discusses the question of whether the iodine-tuberculosis relationship might have been responsible for the reaction, but believes that other factors must be considered. The fact that no reaction appeared until six applications of iodine had been made suggests a process of sensitization. The literature is surveyed and fourteen cases of hypersensitivity to cutaneous applications of iodine are quoted. The mortality rate was 46.9 per cent.

171 Nervous Sequelae of Artificial Pneumothorax

G. Poix and A. Jacquet (*Presse méd.*, May 19, 1937, p. 745) have come to the conclusion that the position of the patient during the production of an artificial pneumothorax may be responsible for the nervous lesions of embolic origin sometimes met with. It was noticed that left hemiplegia caused by a gaseous embolus often developed during the production of a right-sided pneumothorax. Such nervous lesions as convulsions or paralysis were found on the opposite side to the insufflation. Experiments have been carried out to show the course followed by gaseous emboli in the branches of the aorta following a change in the patient's position, and the results confirmed the original hypothesis. When a right-sided pneumothorax is created, the patient is usually lying on the left side, and if an embolus develops it would be expected to follow the direction of the innominate trunk, producing paralysis or convulsions on the left side. This has been found to be the case in thirteen instances. If the patient is in the dorsal or ventral position the left side is usually affected, but in inducing a left-sided pneumothorax with the patient lying on the right side the embolus follows the left common carotid, and nervous lesions appear on the right side. This has also been confirmed in actual cases. When injection is carried out below the clavicle or in the inter-scapulo-vertebral space with the patient in a ventral or dorsal position, the embolus passes along the innominate trunk with localization on the left side, and this was observed in six cases. If the patient departs from the horizontal position the emboli may escape from the cavities of the heart, and may cause delayed symptoms or death. The result of these observations is of value in determining the correct position when producing artificial pneumothorax. If nervous lesions develop during the procedure the patient should be placed either in the prone ventral position, in the horizontal position, or in the Trendelenburg position.

Surgery

172 Acute Pancreatic Necrosis

F. Bernhard (*Beitr. klin. Chir.*, June 9, 1937, p. 513) states that while acute pancreatic necrosis as an immediate sequel to biliary tract operations is so well known that many surgeons have been led to abstain from stretching the papilla of Vater, little attention has been paid to its occurrence months or years afterwards. The removal of gall-stones has been erroneously thought to confer immunity from acute pancreatic disease. Bernhard found, however, six cases of acute pancreatic necrosis occurring since 1900, and following 1,000 choledochotomies and 5,000 cholecystectomies. Nevertheless, surgical treatment of cholelithiasis does diminish the risk of acute pancreatic disease. The surmise that in such cases a stone in the common duct has been overlooked at operation is supported by their greater frequency after cholecystectomy than choledochotomy; in about one-half of the relevant cases in the literature in which exploration of the common duct was carried out at operation or necropsy after acute pancreatic necrosis one or more stones were found. Some reduction in the incidence of this condition would be achieved, Bernhard believes, if after removal of the gall-bladder the common duct were more often opened, explored, and drained. In diagnosis, late post-operative acute pancreatic necrosis may easily be confused with acute biliary peritonitis from perforation of the drainage site or the stump of the cystic duct. This catastrophe usually occurs within the first three months, but may happen as late as three years after operation. In the latter case, however, bile pigments appear quickly and abundantly in the urine and the diastase excretion is but little raised.

173 Anastomotic Ulcer

R. Alesandri (*Zbl. Chir.*, June 12, 1937, p. 1394) analyses 118 cases of post-operative jejunal ulcer seen at the Surgical Clinic in Rome in the past twenty years. The majority of cases occurred in males, aged between 25 and 50, following an operation for duodenal ulcer. In ninety-one cases gastro-enterostomy had been performed, and in twenty-one resection; statistics showed that peptic ulcer

in the jejunum occurred least often after retrocolic gastro-enterostomy in the former and after the Billroth II operation in the latter. The author is convinced that resection of the ulcer-bearing area is the only method which holds out hope of radical cure and prevention of relapses and complications. He has performed the radical operation fifty-three times, on fifteen occasions for post-operative jejunal ulcer. The operation giving the best results has been Billroth II—namely, gastroduodenojejunal resection and end-to-end jejuno-jejunostomy followed by retrocolic end-to-side gastro-enterostomy. The upper limit of the operation is the entrance of the left gastric artery into the stomach wall. The ulcer-bearing area is removed. Following this operation jejunal ulcer occurred in only 1.8 per cent. of the cases. The mortality of radical operation for post-operative jejunal ulcer is 15.3 per cent., and is higher than that of more conservative measures owing to technical difficulties, adhesions, penetration of the ulcer into the colon, mesocolon, or mesentery, and, rarely, perforation. In many cases, too, the patient requires immediate operation while in a low state of health. The author is convinced that the mortality figure of this condition would fall if the Billroth II radical operation was always performed.

174 Malignant Hypertension

L. Friedman and A. A. Eisenberg (*N.Y. St. J. Med.*, June 15, 1937, p. 1131) discuss their results in seven cases of bilateral partial adrenalectomy performed for malignant hypertension. As the aetiology of essential hypertension is controversial and medical treatment merely symptomatic this empirical adrenal surgery was attempted. From 1903 onwards an endeavour has been made by Josue, Vaquez, and later, Crile, to stabilize vasomotor control through the suprarenals, but with disappointing results. A more direct attack was suggested in 1934 by De Courcy by a partial bilateral adrenalectomy with an interval of from three to four months between each operation. The patients operated on were persons between the ages of 20 and 43, with blood pressures in the region of 250/150 mm. Hg and defective urea clearance. All complained of headache, dizziness, nausea, and retinal change; four had myocardial and three kidney damage. Of these seven, only one is alive, with improved health; two died from adrenal insufficiency, one acutely, the other after six months, two from cerebral haemorrhage, and two from subsequent disease. In five cases there was immediate symptomatic improvement, with a fall in the systolic pressure and improved urea clearance; three persons felt that the operation had been worth while. The amount of gland removed in five cases was more than one half, and proved to be within the safety limit; in the sixth, adrenal insufficiency, followed with low blood pressure, rapid pulse, high fever, and later coma. The glands examined showed marked thickening of the capsule and trabeculae, and microscopically hypertrophy of the arterial media.

175 Urinary Complications of Chronic Appendicitis

J. Salleras and A. von der Becke (*Urol. cutan. Rev.*, June, 1937, p. 395), who record two cases in men aged 35 to 45, state that appendicitis is not always a local disease, but like all infectious disorders may affect the whole organism and give rise to reflex phenomena in the urinary system which are toxic or infective in character. Nephritis, albuminuria, and haematuria may be manifestations of appendicitis lasting from a few hours to from two to five days, rarely longer, and disappearing abruptly. The haematuria, which may be renal, ureteral, or vesical, appears in all forms and at all stages of acute or chronic appendicitis. In chronic appendicitis the haematuria precedes the appendicular signs, is variable in amount, and usually has no sequelae. It may be macroscopic or microscopic, painful or painless, and it does not aggravate the prognosis. Surgical treatment is necessary, and consists solely in the removal of the appendix.

Therapeutics

176 Cryptorchism

E. Dahl-Iversen and U. Starup (*Hospitalstidende*, June 15, 1937, p. 657) report from the Rigshospital in Copenhagen their encouraging experiences with a gonadotropic hormone prepared from the urine of pregnant women and given to four boys between the ages of 12 and 16. In two of these cases the retention of the testicles was unilateral, and in the other two bilateral. The authors' survey of the recent literature of this subject shows that nineteen different writers have published 265 cases of undescended testicles treated with hormones. In 208 of these cases accurate reports have been published, and they show that complete descent, associated with growth of the testicle, occurred in 129 cases, or 62 per cent. Partial descent and growth of the testicle was achieved in twenty-five cases; the remaining fifty-four were unaffected. Several of these failures might be explained by the age of the patients—20 to 30—or by some previous unsuccessful operation. Bilateral cases react better to hormone treatment than unilateral cases, presumably because the latter usually depend on some mechanical obstacle to descent, whereas bilateral retention is more commonly due to some endocrine disturbance. In fourteen out of twenty-eight cases in which the physical development was perfectly normal, apart from the failure of the testicles to descend, there was no reaction, whereas there were good results in the overwhelming majority of the cases presenting well-defined clinical evidence of some endocrine insufficiency. The authors conclude that the hormone treatment of undescended testicle must now be considered superior to operative treatment, and they prefer to start treatment about the age of 14 to 15. Their lowest age limit is 12 years, since hormones given under this age are liable to induce precocious puberty.

177 Vitamin C Therapy in Pneumonia

E. Bohnholtzer (*Dtsch. med. Wschr.*, June 25, 1937, p. 1001) prefaces the account of her clinical experiences with arguments justifying the treatment of pneumonia with vitamin C or ascorbic acid. Among them is the observation that pneumonia is most frequent at those seasons in the year in which vitamin C deficiency is greatest. In addition to certain cases of bronchopneumonia and chronic pneumonia, she treated sixteen patients suffering from fibrinous pneumonia. Ascorbic acid was given by intramuscular injection and, later in the disease, by the mouth. This treatment was controlled by ascorbic acid analyses of the urine. During the first few days 400 or 500 mg. were injected three times daily until the temperature had fallen to normal or the appearance of ascorbic acid in the urine showed that the saturation point had been reached. Then, and until recovery, 100 mg. of ascorbic acid were given three times a day by the mouth; the sodium salt of *l*-ascorbic acid was given as this salt is better tolerated than pure ascorbic acid. Other treatment was limited to expectorants and drugs with an action on the cardiovascular system. In no case could ascorbic acid be demonstrated in the urine before treatment was instituted, and it was noted that with the same dosage the interval between the beginning of this treatment and the first appearance of ascorbic acid in the urine was longest when the disease was most severe. In a fatal case of bronchopneumonia this interval was as long as six days. In most cases the first appearance of the ascorbic acid in the urine coincided with a fall of the temperature. Even after the first injection there was often an encouraging response indicated by an improvement in the respiration and in the patient's symptoms, and it was remarkable that all the sixteen cases of fibrinous pneumonia yielded little or no sputum. The fall of the temperature in eight cases was by crisis.

Neurology

178 Dementia Praecox

W. M. VAN DER SCHEER (*Nederl. Tijdschr. Geneesk.*, July 3, 1937, p. 3120) during the last eighteen months has treated eighteen carefully selected cases of dementia praecox at the Groningen University Psychiatric Clinic with the insulin shock treatment advocated by van Sakel of Vienna. The method consists, first, in inducing a hypoglycaemic coma by intramuscular injection of insulin, and then, after it has lasted from one to one and a half hours, in injecting 100 grammes of 30 per cent. glucose intramuscularly, or 50 grammes intravenously. The treatment is continued for two or three months, with a rest day once a week. Of the eighteen cases so treated, seven recovered, five remained unchanged, and six showed some improvement but not complete recovery.

179 H. ARNESEN (*Tidsskr. norske Laegeforen.*, June 1, 1937, p. 569) has investigated the subsequent careers of 815 patients treated for dementia praecox at the Gaustad Asylum in Norway over the period 1915–29. Forty-three of the patients could not be traced, as many of them had accepted work abroad. Of the remaining 772, as many as 143 had recovered, while the rest were dead or still ill. If to this recovery rate of 18.5 per cent. be added a small percentage of the patients who could not be traced, it may be assumed that some 20 per cent. of all the patients recovered. Of these patients only one had been discharged as well, while 106 left the asylum as improved and thirty-six as not cured. A classification of the 143 recoveries according to the nature of the dementia praecox showed that forty-nine of the patients had suffered from catatonia, sixty-three from paranoia, eight from hebephrenia, and twenty-three from forms of dementia praecox that were difficult to classify. After a study of the history of each case ending in recovery the author comes to the conclusion that neither a bad family history nor sexual manifestations give ground for a bad prognosis. Sunstroke, shock due to operations, etc., and economic and social factors also do not seem to influence the prognosis, but drunkenness affects it badly. Prognosis is comparatively good when the origin of the dementia praecox is psychogenic, even when the dementia has lasted a very long time. Among the recoveries there were four patients who had been ill for more than twenty years, and one for more than thirty.

180 Insulin Shock Treatment of Schizophrenia

G. EWALD (*Med. Welt*, June 26, 1937, p. 899) points out that the new treatment of schizophrenia with insulin shock has been received with scepticism owing to the large number of former unsuccessful methods of treatment. He believes that schizophrenia is due to a lesion of the central and autonomic nervous systems, and that Sakel's induction of shock is the most important factor in the new method. He does not believe that this treatment is dangerous provided due care is taken. The amount of insulin capable of producing a state of shock must be found by experiment in each individual. At the beginning of the treatment patients complain of intense hunger; then they fall into a stupor. When a comatose state is reached half a litre of 35 per cent. dextrose is introduced through a stomach tube, and the patients awake in from fifteen to sixty minutes. Usually they are then pleasant, but later relapse into their previous condition. At the end of the course these relapses become less frequent and less well marked. Psychotherapy and regulated work are useful adjuvants in treatment. Epileptic seizures occurring during shock require the immediate injection of adrenaline or intravenous dextrose. Care must be taken in the introduction of the tube and in the prevention of choking from tenacious sputum or vomitus. After an experience with thirty-five cases Ewald comes to the conclusion that although there are many failures no treatment has hitherto effected so much good in so short a time in patients with long-standing schizophrenia. Early cases react best to insulin shock, but it is impossible to say how long the cure will last. In all cases of acute or subacute schizophrenia a course of insulin shock should be tried. This method combines intensive irritation of the higher centres, with laying down of fat in the body, which increases the vitality and strength of the patient. It combines the effects of an artificial interference and a biological reaction.

181 H. SALM (*Münch. med. Wschr.*, July 2, 1937, p. 1046), in a series of eighty cases of schizophrenia treated by insulin shock, has had several patients whom it was impossible to rouse from their coma by giving carbohydrates and adrenaline in large quantities. In some instances the patients were roused but were confused, sleepy, vomited repeatedly, and had a high temperature. Hypoglycaemia does not explain these untoward results, but the author believes that it may give rise to cerebral lesions which are not relieved by the administration of carbohydrates, and are due to a local disturbance of the carbohydrate metabolism in the brain cells. Confusional states and continued sleepiness are due to disturbances of the mid-brain, and are comparable with the clinical picture of epidemic encephalitis. Similarly, the occurrence of sweating and an alternating rapid and slow pulse are due to a disturbance of the extrapyramidal centres. In a case examined at necropsy haemorrhages were found in the region of the third ventricle, in the substantia nigra, and in the vegetative centres which regulate sleep, warmth, blood circulation and pressure, and sweating. These complications cannot be foreseen, and must be treated seriously, since they often end fatally in spite of massive doses of sugar and adrenaline. It is essential to maintain the circulation, and if the pulse remains good and the general condition is maintained, the patient will probably awake, even after a period of several days.

182 Direct Irradiation of Cerebral Tumours

C. A. ELSBURG, L. M. DAVIDSON, and C. G. DYKE (*Bull. neurol. Inst. N.Y.*, 1937, **6**, 1, 32) have made a preliminary report on the technique and results of the direct application of *x* rays to cerebral tumours exposed at operation. Most of the tumours of the glioma group can only be partially removed at operation, their deep subcortical ramifications being untouched. Their sensitivity to *x* rays varies enormously; the posterior fossa medulloblastomas of childhood give a response to deep *x*-ray irradiation after decompression, which appears to be better than removal, while in others, such as the astrocytomata and the glioblastomata, results are usually disappointing. With present methods not only is the liability to necrosis of the scalp and bone great but the tumour receives insufficient irradiation. In order to eliminate these disadvantages a very high voltage was used, and irradiation of irremovable and partially removable tumours was carried out in the operating theatre by direct application of the rays to the cortex through a layer of cellophane. A 200,000 volt 25 milliampere oil-cooled apparatus was used, and an elaborate portable lead screen was arranged in the theatre. In order to establish the maximal safe dose experiments were carried out on monkeys. It was found that over 4,000 *r* units caused definite neuronal destruction, but 3,000 *r* units could be used with impunity. Both the cerebrum and cerebellum were irradiated, smaller doses being used for the former as it was found that cerebral symptoms were more readily evoked, although some of the symptoms were very late in onset. In some cases in which no cerebral symptoms occurred there was depilation and bone necrosis on the side opposite the point of entry of the rays. In the applica-

tion of this technique to man eighteen cases of cerebral tumour were irradiated at operation, and although it is too soon to draw decisive conclusions, the method would seem to justify further trial and study.

183 Shivering

R. Jung, J. Doupe, and E. A. Carmichael (*Brain*, 1937, **60**, 1, 28) have investigated the physiology of shivering in man. They recorded the changes in the blood temperature of normal and abnormal subjects by means of a thermocouple inserted 5 cm. above the anal sphincter; the skin temperature was raised by means of radiant heat lamps and lowered with a blast of air from the fan of a vacuum cleaner directed through an ice container. The relation of shivering to the sensation of cold air on the skin and to the changes in blood temperature was observed. The authors were able to show that shivering occurred with a stable or a rising blood temperature. In a case of transection of the spinal cord they found that the application of cold to the anaesthetic legs and trunk caused no shivering, while the same stimulus given to the normally innervated skin readily induced this phenomenon. The hyperaesthesia to cold of a tabetic did not facilitate shivering. Destruction of the spinothalamic tracts abolished shivering below the level of the chordotomy, whereas damage to the pyramidal tracts had no effect. The character of the clonic movements of shivering was altered by lesions of the cerebellar tracts and by loss of deep sensation. On the other hand, lesions of the cerebral hemispheres had no effect, except on the spastic limbs, which showed the clonic shivering movements more easily. By lowering the blood temperature of a paraplegic patient and immersing the legs in cold water it was shown that shivering only began in the absence of an external sensation of cold when the fall in blood temperature had caused the patient herself to feel chilled. In a normal subject under similar circumstances shivering occurred much earlier. Thus by clinical observation the investigators were able to show that the efferent pathway for shivering lay in the anterolateral columns, and that the affector stimulus was a sensation of cold, either on the surface of the body or as a result of lowering the blood temperature considerably. There was no evidence that shivering is dependent on changes in blood temperature regulating a shivering centre.

Obstetrics and Gynaecology

184 Vitamin C Deficiency in Pregnancy

G. Gaehtgens and E. Werner (*Klin. Wschr.*, June 12, 1937, p. 843) recall that comparative estimations made on the blood of the umbilical vein and artery have proved that the foetus absorbs vitamin C from the placenta. Using the test recently described by Jezler and Kapp—an estimation of the time necessary to bring about the increased urinary excretion of vitamin C after the daily administration of 300 mg. of ascorbic acid—they found that in about 62 per cent. of healthy primiparae and 70 per cent. of healthy multiparae there was a relative vitamin C deficiency. Five or six days instead of four were required for "saturation." After correction for the amount of vitamin C excreted in the milk—6 to 8 mg. per cent.—they found no evidence that lactation, as such, brings about an increased necessity for vitamin C over and above the relative deficiency which previously existed during pregnancy.

185 Conservative Subtotal Hysterectomy

Voiquenne (*Scalpel*, Liége, May 29, 1937, p. 673) points out the disadvantages of carrying out a total hysterectomy in a young woman when a less radical procedure would suffice. Menstruation plays an important psychological part in a woman's life, and the suppression of the ovarian hormones upsets the endocrine equilibrium. It has been found that following a subtotal hysterectomy the menopause occurs before the age of 40 in 80 per cent. of cases, while normally this takes place before that age in only 5 per cent. of women. It is strongly urged that conservative treatment should be carried out whenever possible, and at least one ovary should be left in cases of chronic infection of the uterus and adnexa, and other diseases of the pelvic organs. The various procedures possible are discussed and details are given of a series of twenty-nine cases in which "fundic" hysterectomy was performed. This operation aims at retaining enough ovarian tissue and uterine mucosa for function to be preserved. Of the cases reviewed the end-result was excellent in sixteen instances, or 55 per cent. In these cases the patients were completely cured, and menstruated regularly. The result was considered satisfactory in a further five cases in which menstruation was irregular or had ceased, but there were no other signs of the menopause. In three cases the menopause had occurred, and in three others further intervention was necessary. There were two post-operative deaths, a mortality of 5.5 per cent.

Pathology

186 Culture of the Gonococcus

R. Winkler (*Derm. Wschr.*, July 3, 1937, p. 845) reviews the conflicting reports that have been published concerning the optimal conditions for the culture of the gonococcus. He mentions as additional sources of diagnostic difficulty the facts that occasionally strains are encountered which give results positive in smears and negative in cultures, and that the natural form is said to be a monococcus—the diplococci being a result of exuberant growth of fresh cultures. Anaerobic cultures have recently been recommended, and Winkler strongly confirms their value. Testing the A, C, and D plates of Neumann (*Arch. Derm. Syph.*, Wien, 1936, p. 173), which are respectively aerobic, made airtight with plasticine, and containing 10 per cent. CO_2 as a result of the addition of a fragment of CO_2 snow, he finds that in practice the technique may be simplified by using the A and D plates only. He divides gonococci into (1) aerophile, growing only on A or on ascitic-agar plates; (2) aerophobe, growing only on C and D; and (3) aerolabile, which grow irrespective of oxygen concentration. The three groups are equally common, and some 30 per cent. of all strains grow on C and D plates only. His clinical tests, like others recently reported, show that about one-quarter more cases of gonorrhoea can be recognized when direct microscopic is combined with cultural examination. He prefers blood-water agar plates to ascitic-agar, largely because gonococcal colonies do not produce haemolysis, which facilitates macroscopical decision as to which colonies to examine microscopically. The colonies are conical, non-confluent, bluish-white, and in time they turn yellow or brown.

187 Blood Sedimentation

A. B. Robins (*Amer. Rev. Tuberc.*, June, 1937, p. 763), in reviewing the literature on the blood sedimentation reaction, comes to the conclusion that it is a complex physico-chemical phenomenon depending principally on the relation between cells and plasma. In the opinion of most observers the important factors in the reaction are alterations in the plasma proteins. In a series of fifty-seven cases of chronic non-tuberculous pulmonary disease investigated by the author the erythrocyte sedimentation reaction was found to vary with the changes in the clinical condition of the patient. The variations seemed to run parallel with the extent and severity of the infectious process as manifested in the inflammatory reaction produced. Comparative studies of the value of the erythrocyte sedimentation reaction, the total white blood cell count, the polymorphonuclear percentage, and the ratio of segmented and non-segmented forms of polymorphonuclear cells seem to indicate that the sedimentation rate is the most sensitive index of the clinical course.

HARMLESS TO THE DIGESTION

—but do not imagine that The Doctor's China Tea is treated by some secret process. There is no secret about it. It is simply a blend of the choicest China teas, which happen to contain comparatively little tannin. It is therefore *naturally free* from excess tannin. And for that very good reason it is entirely harmless to the most delicate digestion. For that reason, too, the medical profession approve and recommend it—and of course their patients enjoy its fine, delicate flavour. A generous free sample will be sent to any doctor who would like an opportunity of trying the tea.

THE DOCTOR'S CHINA TEA

Priced at 2/10, 3/4, 4/-, and a super quality at 4/6 per lb. Harden Bros. & Lindsay, Ltd. (Dept. 19), 30-34, Mincing Lane, London, E.C.3.

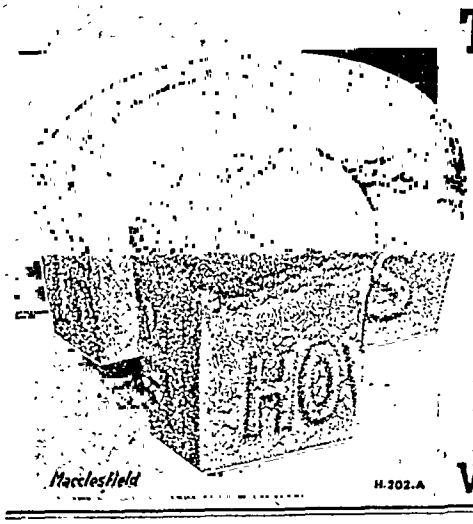
DINNEFORD'S
MAGNESIA

Now obtainable in TABLETS as well as the original Pure Fluid

Made only by DINNEFORD & CO. LTD. 12 CLIPSTONE ST. LONDON, W 1

"MIST. PEPSINÆ CO. c. BISMUTHO"
(HEWLETT'S)

OVER 60 YEARS' REPUTATION.



COMPOSITION.—Pepsin, Bismuth, Sol. Opii Purif., Hydrocyanic Acid (P.B.), Tinct. Nux Vomica, &c.
An elegant preparation, miscible with water, invaluable in Gastric Catarrh, Pyrosis, Carcinoma, and all forms of Atonic and Irritative Dyspepsia.

DOSE: HALF TO ONE FLUID DRACHM DILUTED.

Packed for dispensing only, in 5, 10, 22, 40, and 90- oz. Bottles.
This preparation is also supplied "sine Opio," the dose and price remaining the same.

INTRODUCED AND PREPARED ONLY BY

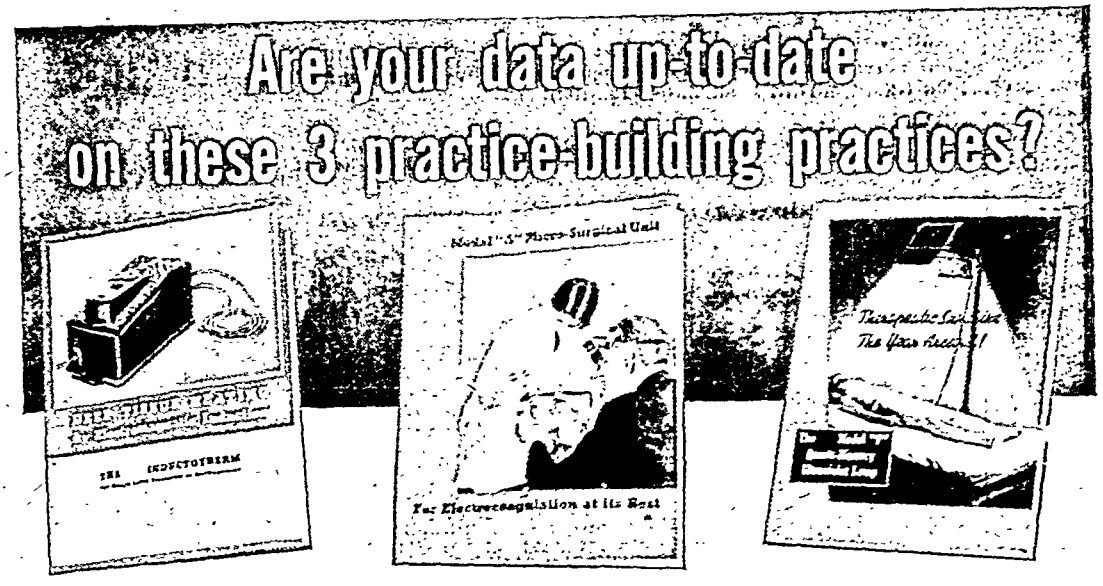
C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte Street, LONDON, E.C.2.

TWENTY-FIVE per cent. of the flour from which the HOVIS TRADE MARK loaf is produced is wheat germ

Science advocates the use of germ-bread as a factor in promoting nutrition. That is why HOVIS figures so prominently upon the dietary when the question of food value must be studied. In white bread, the wheat-germ is practically non-existent. This vitalising source of protein, fats and phosphates abounds in HOVIS. In fact, twenty-five per cent of the flour from which the HOVIS loaf is produced, is WHEAT-GERM. Apart from its low starch-content, HOVIS is practically free from bran and indigestible cellulose. This factor makes HOVIS supreme for easy digestibility and assimilation.

VITAMIN 'B' CONTENT : HOVIS 2,600 WHOLEMEAL 1,450 WHITE BREAD 200

A doctor with a cold !



It is essential that the doctor should avoid colds, although no one is more exposed to infection. The daily use of Vapex is recommended and practised by many medical men. A drop on the handkerchief lasts all day. Most patients know the pleasant, refreshing odour and like to think that their doctor is taking precautions for their safety as well as his own.

THERMOTHERAPY

That inductothermy (electromagnetic induction) is the more efficient agent for thermotherapy, is the conclusion of every comparative test so far published. Yet while the Inductotherm raises body temperatures faster and with greater patient comfort, it costs no more (often less) than common short-wave units that do not give you the Inductotherm's power, versatility, ease of application and economy. The story of Inductothermy and sound evidence of its greater effectiveness is given in an illustrated booklet that is free for the asking; send the coupon for it now.

THERMO-COAGULATION

Extirpation of tonsils and treatment of cervical infections is at once simpler and attended by more satisfactory results when the method used is thermo-coagulation. There is no finer instrument for these profitable procedures than the VICTOR Model "A" Micro-Surgical Unit. The Micro "A," while affording you an exceptionally smooth current under exquisite control, and an infallible means of duplicating techniques, is low in first cost, economical in operation. The coupon will bring you full particulars of this beautiful and useful equipment.

ULTRAVIOLET

In the new Model "F" Ultraviolet Lamp, physicians are offered a fine, dependable, economical source of radiation richest in the preferred wavelengths. This new lamp retains the famous Uviarc burner, but in an improved form. The Model "F" has also been freed from intricacies of control by a modern, simpler design that eliminates unnecessary devices, thus simplifying operation and speeding treatment. Every physician can afford this moderately priced, genuine clinical model ultraviolet lamp. Send the handy coupon to-day for full information and price.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBRIDGE, SUFFOLK**

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. *(Toll Call from London.)*

Proprietors: The Norwood Sanatorium, Limited

RUTHIN CASTLE, NORTH WALES

The fees are from 15 guineas a week. They include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary *x*-ray examinations, and electrocardiograph readings; all treatment that may be prescribed such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing; medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary *x*-ray examination, or for *x*-ray therapy.

All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*—Castle, Ruthin. *Telephone*—Ruthin 66

NORTHAMPTON.
FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.
At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.
For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

TREFRIW (SULPHUR-IRON) WELLS

THE SPA OF OUTSTANDING MERIT

1. These unique waters are of exceptional merit. With other properties they contain Iron as FERROUS-SULPHATE, and in such concentration that the maximum prescribed dose is only ONE OUNCE.
2. Wonderfully efficacious for all forms of rheumatic disease. Many very remarkable results are obtained in severe and chronic rheumatism and rheumatoid-arthritis—even bedridden cases of long standing—from the home treatment alone.
3. A most important feature of this Spa is the bottling of the waters in natural Spa condition for the

SPA CURE AT HOME

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK STREET, LONDON, W.1.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. M.C.CANTAB. (Primary & Final). M.S.LONDON. F.R.C.S.EDINBURGH.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S.England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from these set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

Course starts in September.

Applications to be sent to the undersigned

H. T. RYAN,
Secretary and House Governor.

LONDON HOSPITAL MEDICAL COLLEGE AND DENTAL SCHOOL

THE WINTER SESSION will open on FRIDAY, OCTOBER 1st.

The London Hospital serves the East End of London, and with eight hundred and fifty beds is the largest voluntary Hospital in England. The *Out-patient Department*, which deals with a hundred thousand new patients per annum, is extensively used for teaching.

The size of the Hospital necessitates a large number of resident medical officers. Every year seventy resident house physicians and house surgeons and eighty salaried non-resident clinical assistants are appointed from among recently qualified students. The opportunities which these appointments offer for obtaining clinical experience are invaluable.

The Medical College is attached to the Hospital and is staffed by Professors of Anatomy, Physiology, Bacteriology, Chemical Pathology, Morbid Anatomy and Medicine of the University of London.

Special Courses in Anatomy and Physiology for the *Primary F.R.C.S.* and *advanced courses in* Surgery for the Final F.R.C.S. Examination, and in Medicine for the M.D. and M.R.C.P. Examinations, are held twice a year.

Entrance Scholarships and prizes of the total value of £950 are awarded annually. Research Funds to the value of £113,000 permit of assistance being given to students and graduates engaged in medical research.

The Medical College contains a modern Museum of Pathology and a Library provided with all the current medical periodicals in charge of a full-time librarian. There is also an Athenaeum Club and Dining Hall, a Gymnasium, a Fives Court, and two Squash Courts in the Students' Hostel. The Athletic Ground of 13 acres at Hale End is within easy distance of the Hospital.

The Hospital is only 20 minutes from Charing Cross and Baker Street Stations. For those who wish to live in immediate proximity to the Hospital there is accommodation for sixty students in the Students' Hostel.

Further details may be obtained from the Dean, Dr. A. E. Clark-Kennedy, M.D., F.R.C.P., Physician to the Hospital and Fellow of Corpus Christi College, Cambridge, who is always pleased to meet students wishing to see the Hospital and College and to whom application for admission should be made

Turner Street, London, E.1.

LONDON HOSPITAL MEDICAL COLLEGE

PRIMARY FELLOWSHIP EXAMINATION.

A COURSE OF INSTRUCTION for the above Examination will begin on Wednesday, Sept. 1st.

The fee for the Course is 15 guineas.

Further particulars may be obtained from Dr. A. E. CLARK-KENNEDY, M.D., F.R.C.P., Dean, Turner Street, Mile End, E.1.

THE UNIVERSITY OF SHEFFIELD.

THE UNIVERSITY OF LIVERPOOL

The Council invites applications for the post of LECTURER (ungraded) in the DEPARTMENT OF PATHOLOGY. Salary £300 per annum. The appointment is for one year in the first instance. Applications, together with the names of three referees, should be sent on or before September 10th, 1937, to the undersigned. Further particulars may be obtained from the George Holt Professor of Pathology, to whom inquiries may be addressed.

STANLEY DUMBELL,
August, 1937. Registrar.

THE MANOR HOUSE HOSPITAL, GOLDERS GREEN, LONDON, N.W.11.

Applications are invited for the post of JUNIOR MEDICAL OFFICER. Salary at the rate of £200 per annum, with board residence. Candidates, male and unmarried, must be fully qualified and registered. Applications, stating full particulars and accompanied by copies of not more than three recent testimonials, should be addressed to the undersigned as soon as possible.

JAMES W. FINKHORN, I.C.C.S.,
Secretary.

ROYAL FREE HOSPITAL, GRAY'S INN ROAD, W.C.1

Applications are invited from duly qualified and registered medical women for the following post:

RESIDENT CASUALTY OFFICER.

Duties to commence October 1st, 1937, for six months. Salary £150 per annum. Candidates must have held previous resident Hospital appointments. Application forms may be had from the undersigned, and should be duly filled in and returned on or before September 11th, 1937.

RICHARD T. BARTLEY,
Secretary.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

COUNTY BOROUGH OF WEST BROMWICH.
HALLAM HOSPITAL. (472 Beds.)

HOUSE PHYSICIAN AND HOUSE SURGEON.

Applications are invited from duly qualified male registered practitioners for the above-mentioned posts. The post of House Surgeon will also include duties in the Maternity Wards (30 beds).

The appointments are for six months, with eligibility for a further six months. Either party may give six weeks' notice terminating the appointment. There is a visiting staff of eight physicians and surgeons, one resident surgical officer and three resident medical officers.

Salary £200 per annum, and also board-residence. All fees received by the persons appointed will be payable into the funds of the Council.

Applications, stating age, experience and qualifications, together with copies of three recent testimonials, must be forwarded to the Medical Officer of Health, 2, Lodge Road, West Bromwich, so as to arrive not later than by first post on Saturday, September 4th, 1937.

Canvassing, either directly or indirectly, is strictly prohibited, and will be deemed a disqualification.

Town Hall, ALFRED WICKHAM,
West Bromwich. Town Clerk.
August 20th, 1937.

LANCASHIRE COUNTY COUNCIL.

JUNIOR ASSISTANT MEDICAL OFFICER, WRIGHTINGTON HOSPITAL, APPLEY BRIDGE.

Applications are invited for the post of Junior Assistant Medical Officer (male, unmarried) for the Wrightington Hospital, which contains 205 beds for non-pulmonary tuberculosis (adults and children) and 20 beds for "combined" pulmonary and non-pulmonary cases. Salary £200 per annum, together with board, residence and laundry.

The appointment will commence on October 1st, or thereabouts, and will be for 12 months.

The medical staff consists of medical superintendent, two assistants, two consultant orthopædic surgeons and other visiting surgeons. There are excellent facilities for reading for M.D.

Forms of application and conditions of appointment obtainable from Central Tuberculosis Officer, County Offices, Preston. Letters to be marked "Wrightington M.O."

Closing date September 3rd.

GEORGE ETHERTON,
Clerk of the County Council.
County Offices, Preston.

HOLLAND (LINCOLNSHIRE) COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER OF HEALTH (male or female)

Applications are invited from duly qualified and registered Medical Practitioners (under 40 years of age) for the above appointment.

The salary will be £600 per annum, rising by annual increments of £25 to £700 per annum.

The duties of the post include school medical inspections, the carrying out of work under the Maternity and Child Welfare and Tuberculosis Schemes, and such other duties as may be required by the Council.

The person appointed will devote the whole of his or her time to the duties of the office, act under the direction and supervision of the County Medical Officer, and reside in such part of the district as may be required.

Post-graduate experience in the diagnosis and treatment of tuberculosis and the possession of a Diploma in Public Health will be additional qualifications.

Applications on the prescribed form, obtainable from the undersigned, accompanied by copies of not more than three testimonials, must be addressed to the County Medical Officer of Health, County Hall, Boston, Lincs, and received by him not later than September 7th, 1937.

W. G. BOOTH,
County Medical Officer of Health
County Hall, Boston.
August 7th, 1937.

CITY OF BIRMINGHAM.

DUDLEY ROAD HOSPITAL (926 Beds).

Applications are invited from fully qualified Medical Practitioners for whole-time appointment as JUNIOR MEDICAL OFFICER (male) at the Dudley Road Hospital, Birmingham. The appointment will be for a period of six months, but may be extended for a further period of not exceeding six months. Salary at the rate of £200 per annum and full residential emoluments. The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

Further particulars may be obtained from the Medical Superintendent at Dudley Road Hospital, to whom applications, stating age, experience and qualifications, with copies of recent testimonials, should be forwarded not later than Thursday, September 2nd, 1937.

CITY OF NOTTINGHAM
HEALTH DEPARTMENT

ASSISTANT TUBERCULOSIS OFFICER

Applications are invited for the appointment of Assistant Tuberculosis Officer (whole-time).

Applicants should be registered medical practitioners, preferably holding a Diploma in Public Health, and must have had special experience in the diagnosis and treatment of Pulmonary Tuberculosis, including the use of *X*-rays for diagnosis.

Applicants must be prepared to assist, by lectures and otherwise, in the development of an anti-tuberculosis campaign.

The salary will be on the scale of £500 per annum, rising by annual increments of £25 to £700, but in assessing the commencing salary, allowance will be made for previous service in an established position with another Local Authority.

The salary will be subject to deductions in accordance with the terms of the Local Government and Other Officers' Superannuation Act, 1922.

The successful applicant will be obliged to live within the boundaries of the City of Nottingham, and to terminate the appointment, one month's notice from either side will be required.

Forms of application may be obtained from the undersigned, by whom applications must be received not later than September 6th, 1937.

The Guildhall, J. E. RICHARDS.
Nottingham. Town Clerk.
August 14th, 1937.

Particulars of duties and application form can be obtained from the undersigned to whom such form must be returned not later than first post on Monday, September [illegible] 1937

[illegible] Park [illegible] S. A. JEWERS
August 13, 1937 Town Clerk

WEST RIDING OF YORKSHIRE MENTAL HOSPITALS BOARD.

APPOINTMENT OF MEDICAL SUPERINTENDENT

The West Riding of Yorkshire Mental Hospitals Board invite applications from duly-qualified medical practitioners for the appointment in their service of Medical Superintendent at the Wakefield Mental Hospital.

Candidates must have had previous experience as the Medical Superintendent or Senior Assistant Medical Officer of a Mental Hospital. Preference will be given to candidates who have obtained a Diploma in Psychological Medicine and have served the office of House Surgeon or House Physician at a general hospital.

The person appointed will be required to devote his whole time to the duties of the office and to act in conformity with the provisions of the Lunacy Act, the general rules and regulations of the West Riding of Yorkshire Mental Hospitals Board (as approved by the Board of Control), and of the Wakefield Visiting Committee.

The minimum and maximum salaries fixed for the position are £1,000 and £1,400, the annual increments being £50. The commencing salary to be paid will (within those limits) be according to qualifications and experience.

The person appointed will be provided with an unfurnished house, which will be deemed to be valued, for superannuation purposes, at the sum of £50 per annum. There are no other emoluments attached to the position. The salary and value of the unfurnished house will be subject to deductions under the Asylums Officers' Superannuation Act, 1909.

Application must be made on a form which can be obtained, together with any other particulars, from the undersigned, to whom the completed forms should be returned not later than September 11th, 1937.

Canvassing in any form will be a disqualification.

G. LESLIE BANNER,
Clerk of the Board,
Clerk to the Wakefield Visiting Committee.

Board Offices, Victoria Chambers,
Wood Street, Wakefield.
August, 1937.

THE WEST RIDING OF YORKSHIRE MENTAL HOSPITALS BOARD.
MENSTON MENTAL HOSPITAL, near LEEDS.

APPOINTMENT OF FIFTH ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of Fifth Assistant Medical Officer in the Board's service at the above Mental Hospital, at a commencing salary of £350 per annum, rising by annual increments of £25 to a maximum of £450, together with emoluments (board, apartments and laundry) valued at £120 per annum. The Board will allow an extra £50 per annum to the successful candidate who (whilst on this scale) holds or obtains the Diploma in Psychological Medicine, for which this Hospital affords special study facilities

It will be an advantage if candidates have had at least one year's experience in general medicine after qualification.

The appointment is subject to the provisions of the Asylums Officers' Superannuation Act, 1909, Class 1.

Applications, with copies of not more than two recent testimonials, stating age and full particulars, to reach the Medical Superintendent, West Riding Mental Hospital, Menston, near Leeds, not later than September 6th, 1937.

There is no printed form of application.

G. L. BANNER,
Clerk of the Board.

Board Offices, Wakefield.
August, 1937.

THE ROYAL EASTERN COUNTIES INSTITUTION
for the Mentally Defective, Colchester.

ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the above post, from unmarried male Medical Practitioners not over 35 years of age. Total beds over 1,700.

The medical man appointed will be stationed at the new Extension, Turner Village, and will be required gradually to assume responsibility for administrative work connected with that extension, which has at present over 400 beds. For that reason the commencing salary has been fixed at £400 per annum, together with furnished apartments, board laundry, and attendance. No deductions. Previous specialisation in Mental Deficiency is not essential

A Research Department, with a Medical Director and other Staff, working under the Medical Research Council and the Rockefeller Foundation, is attached to the Institution. New Laboratories costing nearly £5,000 will be ready for occupation in October and there is every facility for research work.

Apply, before September 6th, giving age, [illegible] particulars of qualifications, and names of testimonials, to the Medical Superintendent, Royal Eastern [illegible], Colchester.

COUNTY BOROUGH OF BLACKBURN
PUBLIC ASSISTANCE DEPARTMENT

Applications are invited from Medical Practitioners (male) for the appointment of a RESIDENT JUNIOR ASSISTANT MEDICAL OFFICER at QUEEN'S PARK HOSPITAL and INSTITUTION.

The Staff consists of a Resident Medical Officer, a Resident Assistant Medical Officer, a Consulting Surgeon, a Laboratory Assistant, and an X-Ray Attendant.

There is a separate Infirmary, a separate Mental Block, and a separate Sanatorium for Children, and there is opportunity for experience in all departments, including Medical, Surgical, and Midwifery cases. An X-Ray apparatus is installed.

The person appointed will be required to devote his whole time to the duties and also to act as may be directed by the Resident Medical Officer.

The appointment will be limited to a term not exceeding one year.

Salary for the first six months at the rate of £150 per annum, and thereafter at the rate of £200 per annum, together with board, apartments, and attendance.

Applications, stating age, qualifications, and experience, accompanied by COPIES of not more than three recent testimonials, must be sent so as to reach the Public Assistance Officer, Public Assistance Offices, Cardwell Place, Blackburn, not later than 10 a.m. on September 8th, 1937.

CHAS. S. ROBINSON,
Town Hall, Blackburn, Town Clerk
August 20th, 1937.

LANCASHIRE COUNTY COUNCIL

Booth Hall Hospital—760 Beds.

The Public Health Committee invites applications from registered medical men for the post of RESIDENT ASSISTANT MEDICAL OFFICER at the above-named hospital

The salary for the appointment is £200 per annum, with board, residence and laundry in addition subject to the Manchester Corporation conditions of service

The appointment will be made in the first instance for a period of six months, renewable for a further six months, but NOT beyond that period.

Full information and forms of application may be obtained from the Medical Officer of Health's Department, Lloyd House, Quay Street, Manchester, 3, and all applications for the post must be received by him not later than September 7th, 1937.

C. E. WARBRICK HOSSELL
Town Hall, Town Clerk
Manchester, 3
August 24th, 1937.

CHESHIRE COUNTY COUNCIL
CLATTERBRIDGE (COUNTY) GENERAL HOSPITAL, NEAR BIRKENHEAD.

MEDICAL SUPERINTENDENT.

Applications are invited from duly qualified male medical practitioners, with experience in the administrative control of a public general hospital, for the post of Medical Superintendent of Clatterbridge (County) General Hospital, which Hospital has been appropriated under the Public Health Acts.

The salary will be £1,000 per annum, plus emoluments valued at £150.

Candidates must not be more than 45 years of age. Applicants must hold one of the higher Medical qualifications.

The Medical Superintendent will be required to reside within easy reach of the hospital. He will be an Assistant Medical Officer on the Staff of the County Medical Officer of Health, and will be responsible to the County Medical Officer of Health, and through him to the Management Committee, for the control of the hospital, and for the supervision of the work of the Medical, Surgical, Nursing and other personnel.

The Hospital, which has accommodation for 291 patients and is to be enlarged to accommodate 400, provides treatment for medical, surgical and maternity cases, and has a staff of one deputy-medical superintendent, two resident assistant medical officers, and ten visiting specialists, with a nursing staff of 78.

The appointment will be made subject to the Local Government and Other Officers' Superannuation Act, 1922, and is determinable by three calendar months' notice on either side.

Canvassing, directly or indirectly, will disqualify the applicant.

Form of application and further particulars relating to this appointment can be obtained from the undersigned, and must be returned to him not later than September 15th, 1937.

Public Health Department, IAN MACKAY.
24, Nicholas Street, Chester. County Medical Officer of Health

BRITISH POSTGRADUATE MEDICAL SCHOOL.

There are THREE VACANCIES for HOUSE SURGEONS in the Surgical Unit, British Postgraduate Medical School, Hammersmith Hospital, Ducane Road, W.12.

The appointments are for six months in the first instance, and the holder may apply for a further period of six months. Salary at the rate of £105 per annum, with board, lodging and laundry. Duties to commence on October 1st, 1937.

Duties are mainly in General Surgery, but one appointment is to the Department of Traumatic and Orthopaedic Surgery. It is desirable that applicants should have held a previous House appointment.

Applications, with copies of testimonials, should be sent to the Dean of the School not later than September 13th, 1937.

BRITISH POSTGRADUATE MEDICAL SCHOOL.

Applications are invited from registered Medical Practitioners for the post of CASUALTY OFFICER to commence duty on October 1st, 1937.

The appointment is for six months and non-resident. Salary is at the rate of £150 per annum and the post is specially suited to candidates studying for higher qualifications.

Applications, accompanied by two testimonials, should be addressed to the Dean, British Postgraduate Medical School, Ducane Road, W.12, to arrive not later than first post on Monday, September 6th.

Applications are invited for the post of RESIDENT ANAESTHETIST on the staff of the British Postgraduate Medical School at Hammersmith Hospital (L.C.C.), Ducane Road, W.12. The appointment will be for six months, to commence duty on October 1st, 1937.

Salary will be at the rate of £150 per annum with board, lodging and laundry. Preference will be given to candidates who have held a similar appointment.

Further information can be obtained from the Dean, British Postgraduate Medical School, Ducane Road, W.12, to whom applications accompanied by testimonials, should be sent, to arrive not later than first post on Monday, September 6th, 1937.

CITY OF LEICESTER

RESIDENT MEDICAL OFFICER

Resident Medical Officer (male) required for the City Isolation Hospital and Sanatorium, Groby Road. Appointment for a period of six months. Salary at the rate of £300 per annum, with the usual residential emoluments. The officer appointed may be required to assist with infant welfare work.

Applications, on forms to be supplied, to be sent to the undersigned not later than September 4th, 1937.

C. K. MACDONALD,
Medical Officer of Health
Health Offices, Grey Friars,
Leicester, August, 1937.

CITY OF BIRMINGHAM.
Public Health Department—Tuberculosis Section

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from single registered male medical practitioners for the post of Assistant Resident Medical Officer in the Tuberculosis Section of the Public Health Department. The successful candidate will be employed both in a Sanatorium and in a Dispensary.

Candidates should have held a resident general hospital appointment, and an appointment in some institution recognized for the treatment of the non-pulmonary forms of tuberculosis.

The commencing salary will be at the rate of £450 per annum, rising by £25 to £500 per annum, with emoluments valued at £150 per annum.

The officer appointed will be required to refund to the Council all fees, allowances and emoluments (other than the foregoing) received by him.

The successful candidate will be required to pass an approved medical examination, to contribute to the superannuation scheme established under the Local Government and Other Officers' Superannuation Act, 1922, as amended by Section 82 of the Birmingham Corporation Act, 1935 (Annuities for Widows), and, if under 30 years of age, to join the Birmingham Municipal Officers' Widows' and Orphans' Pension Scheme.

The appointment will be terminable by one month's notice on either side.

Forms of application and a summary of duties may be obtained from, and should be returned with three recent testimonials, to the Chief Clinical Tuberculosis Officer, 151, Great Charles Street, Birmingham, 3, not later than September 9th, 1937.

Council House, Birmingham, 1. F. H. C. WILTSHIRE, Town Clerk.

CITY OF LEEDS

ASSISTANT MEDICAL OFFICER

Applications are invited from qualified and registered Medical Practitioners for the post of Assistant Medical Officer for Maternity and Child Welfare. Applicants must have had not less than three years' post-graduate experience, including experience in General Medicine and Surgery, and special experience in Obstetrics and Ante-Natal work, and in the treatment of Children's Diseases and Diseases of Women. Preference will be given to candidates possessing the D.P.H.

The commencing salary for the post will be £500 per annum, and the present Grading Scheme of the Corporation provides for annual increments of £25, to a maximum of £700.

The person appointed will be required to pass a medical examination, and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922. The appointment will be terminable by one month's notice on either side.

Form of application and particulars as to the duties of the appointment may be obtained from the undersigned.

Applications, endorsed "Maternity and Child Welfare Officer," together with copies of three recent testimonials, must be delivered at the Health Department, 12, Market Buildings, Vicar Lane, Leeds, 1, not later than 12 noon on Saturday, September 4th, 1937.

Canvassing in any form, either directly or indirectly, will be a disqualification.

J. JOHNSTONE JERVIS,
Medical Officer of Health.

DERBYSHIRE EDUCATION COMMITTEE

ASSISTANT SCHOOL MEDICAL OFFICER (male)

The Derbyshire Education Committee require the services of an Assistant School Medical Officer—male—at a salary of £500, rising by annual increments of £25 to £700 per annum, together with a travelling allowance in accordance with the County scale.

Candidates must be registered Medical Practitioners of at least three years' standing. The duties will include work under the Maternity and Child Welfare Service. Experience in this work and in Mental Deficiency is desirable.

The appointment will be a designated post under the Local Government and Other Officers' Superannuation Act and the successful candidate will be required to pass a medical examination.

The Officer appointed will not be allowed to engage in private or consulting practice but will be required to devote his whole time to the duties of the office and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before Monday, September 6th, 1937, endorsed "Assistant School Medical Officer."

The appointment will be terminable by three months' notice on either side.

W. M. ASH,
School Medical Officer.

New County Offices,
St. Mary's Gate, Derby.

WORCESTERSHIRE COUNTY COUNCIL.

ASSISTANT TUBERCULOSIS OFFICER (MALE).

The above-mentioned Council are about to appoint a whole-time Assistant Tuberculosis Officer and applications are now invited for this post.

Applicants must be registered Medical Practitioners between the ages of 25 and 45 years. Special experience and qualifications in Tuberculosis will be necessary, as work under the County Tuberculosis Scheme will form the chief part of the Officer's duties. He should have (1) at least three years' experience in the practice of his profession, (2) spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases, and (3) received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis and in Artificial Pneumothorax treatment. A Diploma in Public Health is desirable. The officer who is appointed will work under the supervision of the Chief Tuberculosis Officer.

The person appointed will be required to reside in the southern half of the County.

The salary will be £600, rising by £25 per annum to £700, with an allowance of £150 per annum for use of his own motor car. The engagement will be subject to three months' notice on either side. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and a medical examination will have to be passed by the successful candidate.

Applications (on forms to be obtained from the County Medical Officer, County Buildings, Worcester), accompanied by not more than three recent testimonials, must be received by 15th day of September, 1937, addressed to the County Medical Officer, County Buildings, Worcester.

Canvassing disqualifies, and neither the names of the members of the County Council nor of the Committee will be supplied.

(Signed) C. H. BIRD,
Clerk of the County Council.

Shirehall, Worcester.
August 21st, 1937. (J. 133.)

COUNTY OF KENT.

ASSISTANT TUBERCULOSIS OFFICER (male).

Applications are invited for the above-mentioned whole-time appointment on the staff of the Public Health Department.

The duties will include attendance at dispensaries, clinical supervision of sanatorium beds, and such other work as may be assigned from time to time.

The salary is at the rate of £600 a year, rising, subject to satisfactory service, by annual increments of £25, to a maximum of £750 a year, with subsistence and travelling allowances, according to the county scale.

The post is designated as an established one under the Local Government and Other Officers' Superannuation Act, 1922, and is terminable by three months' notice on either side. The successful candidate will be required to pass a medical examination.

Applications, stating age, qualifications and clinical experience, with special reference to practical experience in the diagnosis and treatment of tuberculosis, accompanied by copies of not more than three testimonials, must be received by the County Medical Officer of Health, Sessions House, Maidstone, not later than Tuesday, September 7th, 1937. No official form of application will be issued.

The successful candidates (with the exception of the Senior Resident Medical Officer) will be elected for a period of six months and will be eligible for re-election for a further period of six months.

Applications, stating age, qualifications, etc., with copies of three testimonials, must reach the undersigned not later than the first post on Wednesday, September 8th, 1937.

S. C. W. DISNEY,
August 23rd, 1937. Secretary-Superintendent.

CORNELIA AND EAST DORSET HOSPITAL, POOLE, DORSET.
(117 Beds)

HOUSE PHYSICIAN.

Applications are invited (from single men) for the post of House Physician.

Period six months. Salary at the rate of £150 p.a., with usual emoluments. Re-appointment may be applied for, and if granted the salary is at the rate of £175 per annum.

Duties to commence October 1st, 1937.

The Hospital is recognised by the Royal College of Surgeons of England in connection with the Final Examination for the Fellowship.

Applications, stating age, nationality, experience and qualifications, together with copies of three recent testimonials (which will not be returned), should reach the undersigned at the Hospital immediately.

Preference will be given to applicants who have already held a Resident appointment in a Hospital.

E. S. FOLEY,
Secretary.

NORTH WALES COUNTIES MENTAL HOSPITAL, DENBIGH.

The Visiting Committee invite applications from duly qualified male candidates, unmarried, for the post of JUNIOR MEDICAL OFFICER. Commencing salary, which will be subject to statutory deductions under the Provisions of the Asylum Officers' Superannuation Act, 1909, will be £350, rising by annual increments of £25 to £450 per annum, together with full board, residence, laundry and attendance, valued at £125 per annum for superannuation purposes. The appointment to be terminable upon one month's written notice on either side.

A knowledge of Welsh is desirable.

The person appointed will also be paid in addition to his salary the sum of £50 per annum if he holds the Diploma of Psychological Medicine.

Applications, stating age, qualifications, and accompanied by three recent testimonials, are to be sent to the Chairman of the Visiting Committee, endorsed "Junior Medical Officer," not later than Saturday, September 11th.

Dated this 19th day of August, 1937.

WM. BARKER,
Clerk to the Visiting Committee.

MANCHESTER EAR HOSPITAL.
Grosvenor Square, All Saints'.

The Board invite applications for the post of RESIDENT HOUSE SURGEON (31 beds)
Salary £120 per annum. Candidates must be duly qualified and registered.

Applications, with copies of four recent testimonials, to be forwarded to Mr REGINALD S. MILFORD, Hon. Sec., Manchester Ear Hospital, c/o Mr. W. J. ELLAM, 17, Brazennose Street, Manchester, 2.

MEATH HOME OF COMFORT FOR EPILEPTIC WOMEN AND GIRLS, GODALMING.

PART-TIME MEDICAL OFFICER is wanted for the Meath Home (98 Beds) in September. Salary not less than £100 a year.

Experience in treatment of Epilepsy is looked for.

Apply, Secretary, Meath Home, Godalming, Surrey.

BURY INFIRMARY (LANCS).
(127 Beds)

HOUSE PHYSICIAN AND TWO HOUSE SURGEONS.

Vacancies, as above, arise on the Resident Medical Staff, and applications are invited for the posts.

The Resident Staff consists of an R.S.O., a House Physician, and two House Surgeons.

The appointments are for a term of six months, and the salaries payable are at the rate of £150 per annum, with board, residence and laundry, the salary being increased to £175 per annum in the event of a re-appointment to the same or some other office for a further period of six months.

The services of one House Surgeon are required immediately, whilst the services of the second House Surgeon and the House Physician are required about September 20th.

Applications, stating age, qualifications, and nationality, together with copies of three recent testimonials, are to be forwarded to the undersigned as soon as possible, endorsed appropriately "House Surgeon," or "House Physician."

Full particulars of duties may be had on application.

H. WILKINSON,
Superintendent.

MANCHESTER ROYAL INFIRMARY.

RESIDENT CASUALTY OFFICER (*Male*).

The Board of Management of the Manchester Royal Infirmary *invite applications for the above* appointment.

Applicants must hold a Medical and Surgical qualification and be registered.

The appointment is for twelve months subject to the provisions of the bye-laws as to notice.

Salary is at the rate of £150 per annum, with allowance for laundry.

Applicants must state age and send twelve copies of their application and testimonials to the undersigned not later than 9 a.m. Thursday, September 9th, 1937.

By Order.
W. R. TINDALE,
General Supt. and Secretary.

August 23rd, 1937.

ROYAL BERKSHIRE HOSPITAL, READING.

The following Resident appointment will become vacant on October 1st, 1937:

RESIDENT MEDICAL OFFICER (*male*) at the Blagrave Branch Hospital and Assistant to Pathologist (combined appointment). To reside at and have charge of 64 beds at Branch Hospital and to work as Assistant in the Pathological Department of the main Hospital. (Previous experience in Pathology not essential.) The appointment is for six months, and candidates must be fully qualified and registered.

Remuneration at the rate of £150 per annum, with board, residence and laundry.

Applications, stating age and experience, with copies of testimonials, to be sent to the undersigned on or before Saturday, September 11th, 1937.

H. E RYAN,
Secretary and House Governor.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE

The General Committee invite applications for the appointment of a WHOLE-TIME BIOCHEMIST. The successful applicant will be appointed in the first instance for a period of three years, at a salary at the rate of £600 per annum—at the end of this period the holder of the post will be eligible for further terms of re-appointment. Preference will be given to applicants possessing medical qualifications.

Applications, accompanied by sixteen copies of each of three recent testimonials, to be sent to the undersigned on or before Monday, September 13th.

Personal canvass of the Committee is expressly forbidden.

J. A. BEARDSALL,
Secretary-Superintendent

THE STAFFORDSHIRE GENERAL INFIRMARY, STAFFORD.
(*100 Beds*)

Secretary.

THE BOLTON ROYAL INFIRMARY.
315 Beds, including two Auxiliary Hospitals.

Applications are invited from ladies for the post of HOUSE SURGEON. Duties to commence on October 1st, 1937, and include charge of Children's Wards, Ear, Nose and Throat and Gynaecology.

The appointment is for six months, and is renewable. Salary £150 per annum, with board, residence and attendance.

Applications for the post, stating age, nationality, and previous experience, together with copies of testimonials, should be forwarded to the undersigned not later than Tuesday, September 7th.

H. CORLESS,
Acting Secretary.

COUNTY BOROUGH OF IPSWICH.

ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Council invite applications for a whole-time Assistant Medical Officer of Health and School Medical Officer. Applicants may be of either sex, but must be fully qualified medical practitioners possessing a Diploma in Public Health and be under 40 years of age.

The salary will be at the rate of £600 per annum, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £700.

The Council have adopted the Local Government and Other Officers' Superannuation Act, 1922, and the appointment will be a designated post thereunder as from April 1st next. The successful candidate will be required to pass a medical examination.

The duties will be principally those of a School Medical Officer, but the person appointed will also be required to work in other departments at the discretion of the Medical Officer of Health.

The appointment is determinable by three months' notice from either side.

Forms of application may be obtained from the Medical Officer of Health, Public Health Department, Elm Street, Ipswich, and applications with copies of not more than three recent testimonials must be delivered to the undersigned not later than September 30th, 1937, in an envelope marked "Appointment of Assistant Medical Officer of Health, etc."

Canvassing directly or indirectly will be a disqualification.

Town Hall, Ipswich. A. MOFFAT, Town Clerk.

August 24th, 1937.

HERTFORDSHIRE COUNTY COUNCIL.

PUBLIC ASSISTANCE. COUNTY INSTITUTION, OSTER HOUSE, ST. ALBANS.

HOUSE SURGEON.

Applications are invited for the post of House Surgeon (either sex) at the above Institution, which comprises general medical and surgical wards, with separate Maternity and Children's Units.

Salary will be at the rate of £175 per annum, with an allowance of £3 3s. per week until such time as board and residence can be provided in the Institution. The appointment will be limited to one year, and not renewable. The House Surgeon must, until quarters in the Institution are provided, reside near the Institution at an address to be approved by the Guardians' Committee.

Candidates must be duly qualified and registered.

Applications, stating age, qualifications and experience, with copies of not more than three recent testimonials, should be sent to the Clerk of the St Albans Guardians' Committee, Oster House, St. Albans (from whom any further details may be obtained), as soon as possible.

Hertford, Herts. ELTON LONGMORE, Clerk of the County Council.

August 28th, 1937

ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY, WIGAN. (180 Beds.)

Wanted for twelve months, commencing October 1st, 1937, RESIDENT MEDICAL and SURGICAL OFFICER and REGISTRAR. Candidates must have held previous Resident appointments at a Hospital. Preference will be given to those possessing the F.R.C.S. or M.S. Degree. The salary is at the rate of £250 per annum, with board, residence and laundry. Applications, giving proof of registration and not more than three testimonials, to be sent to the undersigned as soon as possible.

A. STANLEY BRUNT, General Superintendent and Secretary.

August 12th, 1937.

WESTERN OPHTHALMIC HOSPITAL, Marylebone Road, N.W.1.

Applications are invited for the following resident posts: (1) SENIOR HOUSE SURGEON, salary at the rate of £150 p.a. (2) JUNIOR HOUSE SURGEON, salary at the rate of £100 p.a. Previous ophthalmic experience required. The selected candidates will be required to commence duties on October 1st and November 1st respectively. This Hospital is recognized for the purposes of the D.O.M.S. Examinations.

Applications, with copies of three recent testimonials, should reach me by September 15th.

H. W. BURLEIGH, Honorary Secretary.

DURHAM COUNTY HOSPITAL (100 Beds)

MALE HOUSE SURGEON required. Duties to commence October 1st, 1937.

Salary at the rate of £150 per annum, with board, residence, and laundry.

Appointment for six months, subject to renewal for a similar period.

Applications, stating age, experience, and enclosing testimonials, should be addressed to the undersigned immediately.

NORMAN BROWN, August 23rd, 1937. Secretary.

COUNTY BOROUGH OF SMETHWICK. ST. CHAD'S HOSPITAL, BIRMINGHAM.

HOUSE SURGEON.

Applications are invited from registered medical practitioners for the appointment of House Surgeon at the Council's Municipal Hospital. The appointment will be for a period of six months, with a salary at the rate of £150 per annum, with the usual emoluments. If the successful candidate is reappointed for a further period of six months, the salary will be at the rate of £200 per annum. St. Chad's Hospital contains 145 beds, and the cases treated include general medical, acute surgical, and maternity patients. It is staffed by the Honorary Consultants of the Birmingham teaching hospitals.

Form of application may be obtained from the Medical Superintendent, St. Chad's Hospital, Hagley Road, Birmingham, 16, to whom applications, endorsed "House Surgeon" and accompanied by copies of three recent testimonials, must be delivered not later than first post on September 11th, 1937.

Canvassing, directly or indirectly, will disqualify.

Council House, Smethwick. FRANK CHAPMAN, Town Clerk.

August 24th, 1937.

CARDIFF ROYAL INFIRMARY. (Associated with the Welsh National School of Medicine.)

Applications are invited for the post of:

RESIDENT SURGICAL OFFICER.

Duties will include case-record keeping and teaching, and surgical work under the direction of the Honorary Staff.

Candidates must be Masters in Surgery of a University of the United Kingdom, or Fellows of one of the Royal Colleges of Surgeons in the United Kingdom, and must have previously held a Resident hospital post.

The salary will be at the rate of £200 per annum, with board, residence and laundry. The appointment is for one year, and the holder will be eligible to apply for reappointment, and may retain office for three consecutive years.

Further particulars may be obtained from the Medical Superintendent, to whom applications (endorsed "R.S.O."), with not more than three testimonials (copies), must be sent by noon on Friday, September 10th, 1937.

By Order of the Council, R. ARMSTRONG, Medical Superintendent.

HUDDERSFIELD ROYAL INFIRMARY. (321 Beds.)

MALE CASUALTY OFFICER required to commence duty on September 5th, 1937.

Salary £200 per annum, with board, residence and laundry. Appointment for six months. Prospects according to qualifications, experience and satisfactory service.

The Hospital is officially recognized for the surgical practice required of non-members before admission to the Final Fellowship Examination of the Royal College of Surgeons of England.

The post of Casualty Officer is next in seniority to that of Resident Surgical Officer.

Applications, with copies of three recent testimonials, to be addressed to the undersigned immediately.

Suitable accommodation available consisting of consulting room, dispensary, waiting room, the remainder being sub-let for £280 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £150 fittings, fixtures, drugs, etc.
25. CITY PRACTICE.—Lock-up, hours 10-1 and 5.30-6.30, producing about £1,000 p.a., including £200 from Panel and appointments. Suitable accommodation available.
26. BAYSWATER.—PRACTICE, established some 65 years for disposal. Gross receipts about £1,440 p.a., with 1,000 Panel patients. Suitable house on lease at £130 p.a. Premium 2 years' purchase.
27. ESSEX COAST TOWN.—A ONE-THIRD SHARE is offered to a physician in an old-established Practice producing about £7,200 p.a. Panel produces about £900 p.a. Consultations 3/6 to 7/6. Visits 5/- to 21/-. There will probably be a choice of houses. Ingoing partner should be aged 35 or over and must have a good hospital experience. He should hold the M.D. or M.R.C.P.
28. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be 28-40, preferably hold a degree and must have their English Fellowship. Premium 2 years' purchase.
29. LONDON, S.W.—Old-established PRACTICE producing £1,500 p.a., with panel of 1,266 patients for disposal. Appointment and small club bring in about £85 p.a. House available contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. Premium £3,000.
30. NORTH-WEST COAST.—SEASIDE TOWN.—CONSULTING PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320. Minimum fee 2 gns. Suitable rooms available at inclusive rental of £64 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1½ years' purchase on actual receipts for first year.
31. *HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE* held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc. Professional accommodation. Good garden and garage. Rent £55 p.a. Prem £1,250.
32. LONDON, SOUTH-EAST.—Middle-class PRACTICE held by vendor nearly 30 years, averaging over £700 p.a. Panel of 576 and one appointment worth £25 p.a. Roomy house with good garden and garage. Leasehold for sale.
33. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¾ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house might be rented for a short period.
34. LONDON.—WESTERN [illegible] PRACTICE producing about £1,100; [illegible] for a young man who will [illegible] 0/6. Small compact house on rental. Premium £1,800.
35. SOUTH-COAST SEAPORT.—Long-established PRACTICE for disposal owing to Vendor's retirement. He has held it for the past 39 years. Income last year *approximately £573 with a Panel of about 460 patients.* Vendor previously held a public appointment producing £450 p.a., which he relinquished owing to age limit. It is considered that anyone devoting whole time to the Practice would increase the receipts. Suitable accommodation available on rental.
36. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last twelve months over £1,300 p.a. Fees 3/6 to 21/-. New house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, garage. Price for freehold £1,300. Sport of all kinds and schools within reach.
37. EAST ANGLIA—WITHIN REACH OF TWO GOOD TOWNS.—Old-established, unopposed country PRACTICE, averaging over £1,000 p.a., including Panel producing over £450 a year. Low expenses. Detached house *in own grounds, containing 2 sitting rooms, 5 bedrooms, etc.* Rent £60 a year. Premium £1,750.

Elastoplast Elastic Strapping Plaster

This illustration depicts the exceptional elasticity which is characteristic of all 'Elastoplast' products. The plaster stretches readily to nearly twice its original length.

'Elastoplast' Elastic Adhesive Plaster is preferred on account of its extreme adaptability and ease in handling.

The 3-yard lengths (stretching to 5/6 yards) can be had on metal spools in tins, or on the convenient SNAP SPOOLS, widths ½", 1" and 1½". 1-yard lengths (stretching to 1¾/2 yards) are available on card cores in tins. Free samples on request to Dept. B.15, T. J. Smith & Nephew Ltd., Neptune Street, Hull.

FAMOUS TEXTBOOKS Published by Saunders

"MACCALLUM" Textbook of Pathology

"The book expresses the personal impression of a pathologist of ripe experience. We feel with this book that the writer is dealing with what he has himself seen and pondered. The publishers have given us a book it is a joy to handle, and the author a book it is a joy to read."
—SOUTH AFRICAN MEDICAL JOURNAL.

NEW (SIXTH) EDITION

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University. Octavo of 1277 pages. 697 Original Illustrations, many in colours.
Cloth, 42s. net.

"HOWELL" Textbook of Physiology

"The subject matter is presented in a straightforward way, with great ease of expression; yet no explanation is shirked which is necessary for its proper understanding. The book is . . . ideal for the student beginning his study of physiology and for anyone who desires a coherent framework on which to build future knowledge."—LANCET.

NEW (THIRTEENTH) EDITION

By WILLIAM H. HOWELL, Ph.D., M.D., Emeritus Professor of Physiology, Johns Hopkins University. Octavo of 1150 pages. 308 Illustrations, many in colours. Cloth, 30s. net.

"HARROW & SHERWIN" Textbook of Biochemistry

"The articles are distinguished not only for the care and accuracy with which they have been written, but also for their comprehensiveness and the lucid manner in which the latest developments of the subject are discussed. In short, it confirms expectations based upon the reputations of the several authors"—BRITISH MEDICAL JOURNAL.

BY 31 TEACHERS

Edited by BENJAMIN HARROW, Ph.D., Associate Professor of Chemistry, The City College, College of the City of New York; and CARL P. SHERWIN, M.D., Sc.D., Dr P.H., LL.D., Member of the Staff of St. Vincent's and French Hospitals, New York. Octavo of 797 pages, Illustrated.
Cloth, 25s. net.

"MAXIMOW & BLOOM" Textbook of Histology

"Of recent text-books on histology, this work, initiated by the late Prof. Maximow and completed by his colleague Prof. Bloom, is by far the most stimulating and instructive, and it is not surprising that there should be a demand for a second edition within three years of its appearance. The book has been thoroughly revised."—THE LANCET.

SECOND EDITION

By ALEXANDER A. MAXIMOW and WILLIAM BLOOM, Associate Professor of Anatomy, University of Chicago. Octavo of 662 pages. 530 Illustrations, some in colours.
Cloth, 30s. net.

"RANSON" Anatomy of Nervous System

"At times the reviewer feels a more than usual lively gratitude towards his editor for introducing to his notice an especially good book. This is one of the times. . . . The great charm of Ranson's book is its thoroughness. . . . All students of neurology will find this book almost invaluable"—IRISH JOURNAL OF MEDICAL SCIENCE.

FIFTH EDITION

By STEPHEN W. RANSON, M.D., Professor of Neurology, Northwestern University Medical School. Octavo of 501 pages. 341 Illustrations, some in colours.
Cloth, 27s. 6d. net.

"AREY" Developmental Anatomy

"Dr. Arey has presented his subject clearly and concisely, and much of this success is due to the numerous simple and carefully labelled illustrations, many of them new, which abound in this volume. Should prove a very welcome addition to the medical student's library, and will be especially useful to those studying for a degree"
—GLASGOW MEDICAL JOURNAL.

THIRD EDITION

By LESLIE B. AREY, Ph.D., Professor of Anatomy, Northwestern University. Octavo of 593 pages with 1188 Illustrations on 547 figures, many in colours.
Cloth, 27s. 6d. net.

THE PRACTITIONER

Founded in the  *Year 1863*

EDITORS

Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D., F.R.C.P., and Alan A. Moncrieff, M.D., F.R.C.P.

The policy of the Editors of *The Practitioner* is to provide a programme of practical articles dealing with treatment, and each number is planned to be of value to the practitioner in his daily work. Every month the medical literature of the World is surveyed and important advances recorded. An interesting section is entitled "Notes and Queries" in which illuminating answers are given to problems presented by readers. Two Special Numbers are published each year (at 7s. 6d. each) and are included in the annual subscription rate of £2 2s. The next will be published on October 1st and will be entitled:—

ADVANCES IN DIAGNOSIS AND TREATMENT, 1937

In this Special Number there are twenty-two articles contributed by the recognized authorities on the various branches of medicine. Among the important advances of the year which are critically reviewed are the anti-streptococcal group of drugs, and benzedrine sulphate.

DIET IN HEALTH AND DISEASE

In each issue appears an article under this heading dealing in a practical manner with dietetic problems. A profusion of detailed diets are published in a form which can be conveniently copied for the use of patients.

SUBSCRIPTION FORM

To the Publishing Department, THE PRACTITIONER, 5, Bentinck Street, London, W. 1.

I enclose £2 2s. Please send to me *THE PRACTITIONER*, post free, for one year; subscription to include two Special Numbers without extra cost.

ON THE SUBJECT OF CRIME

CRIME is a subject of perennial interest to students of Social Hygiene. Its causes and prevention are the subject of innumerable volumes whilst its detection in real life and fiction is of never failing interest. The Ruxton Case had many astonishing features and was one of the few crimes in which all the resources of the police and the medical profession were harnessed to secure the evidence necessary for final conviction.

In MEDICO-LEGAL ASPECTS of the RUXTON CASE

a work which has been undertaken by Professor John Glaister, M.D., D.Sc., Barrister-at-Law, and Professor James Couper Brash, M.A., M.D., in response to numerous requests, the authentic account of the medical and scientific investigations is fully given and extensively illustrated.

READY SEPTEMBER. Crown Quarto, 320 pp., 172 illus. Price 21/- net, postage 7d.

Illustrated prospectus free on application.

NEW BOOKS

SIMSON HALL

Diseases of the Nose, Throat, and Ear

Just Issued.

A TEXTBOOK OF DIAGNOSTIC ROENTGENOLOGY

LEWIS J. FRIEDMAN, M.D.

In this new book Dr. Friedman supplies the long-needed complete treatise on roentgenology. He gives a thorough and complete analysis of all aspects of the subject, beginning with the consideration of the theoretical and material phases of the X-ray machine and then continuing with a well-rounded discussion of techniques and their rationales, a discussion of X-ray physics and its practical application, descriptions of all diagnostic problems, and the considerations of the aetiology, pathological changes and roentgenographic descriptions of the various diseases.

650 pages. 483 Illustrations. **42/-.**

LEGAL MEDICINE AND TOXICOLOGY

T. A. GONZALES, M.D., MORGAN VANCE, M.D., & MILTON HELPERN, M.D.

With an introduction by Harrison S. Martland, M.D.

A thoroughly modern consideration of legal medicine with an equally up-to-date exposition of toxicology. Particularly noteworthy are the chapters on the special technical processes used in medico-legal investigations, such as examinations of blood and iso-agglutination tests. Throughout, the subject has been treated from the viewpoint of the physician in practice. Material outside of his sphere has been eliminated, or simply sketched in for unity and coherence. By no means the least remarkable features of this volume are the illustrations, they cover the subject with unequalled scope and a technical excellence that contributes greatly to the usefulness of the volume.

757 pages. 211 Illustrations. **42/-.**

D. APPLETON-CENTURY COMPANY, 34 BEDFORD STREET, LONDON.

HEFFER

A MANUAL OF RADIOLOGICAL DIAGNOSIS FOR STUDENTS AND GENERAL PRACTITIONERS

By IVAN C. C. TCHAPEROUT, M.A., M.D., D.M.R.E. (Camb.), Assistant Radiologist and Radium Registrar, St. Thomas's Hospital, London. With a Foreword by PHILIP H. MITCHINER, M.D., M.S., F.R.C.S., Surgeon to St. Thomas's Hospital. Cr. 4to, cloth, illustrated, 21s. net.

"This is an excellent book . . . the author is to be congratulated on . . . the magnificent illustrations, of which there are 286. . . . We can recommend this book to the student and practitioner and to those physicians and surgeons who still examine with care the radiograms of their patients. It would even fill a valuable niche as a book of reference on the radiologist's bookshelf. It will serve as a standard for many years."—*Clinical Journal.*

An 8 pp. illustrated Prospectus is available.

Ready shortly

SURFACE AND X-RAY ANATOMY

By A. B. APPLETON, M.A., M.D. (Cantab.), M.R.C.S. L.R.C.P., F.Z.S., Professor of Anatomy, St. Thomas's Hospital, University of London; W. J. HAMILTON, P.D.Sc.; and IVAN C. C. TCHAPEROFF, M.A., M.D., D.M.R.E. (Camb.), Assistant Radiologist and Radium Registrar, St. Thomas's Hospital, London. Demy 8vo, cloth. Illustrated. Probably 12s. 6d. net.

The importance of studying anatomy with the help of X-rays is now generally recognised. A knowledge of "*normal*" Radiological appearances is indispensable as a background for the proper utilisation of X-rays for clinical purposes. The medical student and the practitioner are here provided with a text-book in which the essentials of normal radiological anatomy are shown in relation with the facts of anatomy derived from dissection and surface examination.

The book is copiously illustrated with reproductions from radiographs and photographs. The drawings are from the pencil of a well-known anatomical artist.

STEROLS AND RELATED COMPOUNDS

Three Lectures. By T. FRIEDMANN, M.D., Ph.D., formerly Professor of Biochemistry in the University of Berlin. Foreword by SIR FREDERICK GOWLAND HOPKINS. Royal 8vo, cloth. 7s. 6d. net.

One of the most striking advances made in Biochemistry in recent years has been the recognition of the varied functions carried on in living matter by substances belonging to the chemical group of Sterol. The present book, based on three Lectures delivered at the Institute of Biochemistry, gives a brief survey of the rapid advance recently made in this field.

ARTIFICIAL PNEUMOTHORAX

Fourteen years ago the Medical Research Council issued a *Report on Artificial Pneumothorax* (No. 67, 2s. 6d. (2s. 8d.)). Since then the method of treatment has had extended use and an account is now presented of the experience of the London County Council between the years 1920 and 1930. The data are subjected to a detailed statistical analysis which throws much light on the value of this form of collapse therapy. A critical review of the extensive literature of the subject is included. Special Report No. 215. 1s. 6d. (1s. 8d.).

X and γ RAYS

SOME QUANTITATIVE ASPECTS OF THE BIOLOGICAL ACTION OF X AND GAMMA RAYS

A quantitative study of the action of X and gamma rays on different types of living cells has important bearings on the use of the rays in the treatment of cancer. This analysis of the physical and biological problems involved, and summary of attempts at solving them, includes a brief description of some ingenious and well-planned experiments and concludes with an interesting and informative discussion on the results obtained. Medical Research Council Report 223. 1s. 6d. (1s. 8d.).

HEART DISEASE

THE DEVELOPMENT OF CARDIAC ENLARGEMENT IN DISEASES OF THE HEART

Shows by means of X-ray examinations the ultimate effects upon the heart's size of such major events as persistently increased heart-rate, high blood pressure, congestive failure, and coronary thrombosis. The grouped descriptions of cases should have permanent value in providing for reference direct examples and clear details of changes of the heart's size in many different types of patient. Medical Research Council Special Report No. 222. 1s. (1s. 2d.).

THE DEAF

HEARING AND SPEECH IN DEAF CHILDREN

This account of fundamental research now available as *Special Report No. 221 of the Medical Research Council* should be of assistance to all concerned with the treatment and education of deaf children. 2s. (2s. 3d.).

The report follows a previous Special Report No. 219 on "THE USE OF HEARING AIDS" (9d., post free 10d.), a pioneer investigation into the characteristics of efficient hearing aids. The author of the new report estimates that three-quarters of the deaf children in the country could be helped by scientific use of the right instruments.

MATERNAL MORTALITY

Two reports have recently appeared on this subject, one devoted especially to conditions in Wales where maternal mortality is high, the other to England. The documents are essentially practical and concentrate upon remedial measures in areas where mortality is highest. A working scheme is outlined whereby local authorities should co-ordinate the work of health visitors, midwives and doctors—whether in general practice, attached to hospitals and clinics, or specialists. Each report contains numerous statistics. Report for England, 353 pages. 5s. (5s. 11d.). Report for Wales, 156 pages. 2s. 6d. (2s. 9d.).

All prices are net. Those in brackets include postage.

DISEASES OF THE HEART

Described for Practitioners and Students.

By

Sir Thomas Lewis

F.R.S., M.D., F.R.C.P.

Physician in Charge of Department of Clinical Research, University College Hospital, London.

The text of the first edition has been revised thoroughly, and all recent and relevant advances in our knowledge, which it is judged will prove of value to practitioners, have been incorporated.

REVIEWS OF THE FIRST EDITION

"The information is presented with a simplicity and economy of detail, the value of which will be appreciated by those who have found little help from more wordy explanations. . . . Is essentially stimulating."—*The Lancet.*

"He has demonstrated the importance of clear thinking and true reasoning, based upon sound physiological principles. In this compact volume are laid down the fundamental principles of circulatory derangement as they are understood today."—*British Medical Journal.*

MACMILLAN & CO. LTD., ST. MARTIN'S ST., LONDON, W.C. 2

FEEDING BEHAVIOUR OF INFANTS

by ARNOLD GESELL, Ph.D., M.D., Sc.D., and FRANCES L. ILG, M.D.

200 Illustrations. 21/-

The normal and near-normal deviations of feeding behaviour of infants are treated in this volume. Although non-technical, it has been written particularly for the physician and child hygiene nurse. It focuses attention on the medical importance of infant feeding behaviour and on important new possibilities of diagnosis and regulation.

MEDICAL STATE BOARD EXAMINATIONS

Topical Summaries and Answers

An Organized Review of Actual Questions given in Medical Licensing Examinations throughout the United States.

by HAROLD RYPINS, A.B., M.D., F.A.C.P.

Third Edition Revised. 21/-

This book is the result of ten years' experience with candidates for admission to the practice of medicine, and has been written in response to repeated requests from them for guidance.

The Newest Thing in Medical Literature

DIGEST OF TREATMENT

General Editor: GEORGE E. REHBERGER, M.D.

Volume I. September, 1937. No. 3.

Through *Digest of Treatment* the busiest physician can learn the latest developments in treatment by spending a few spare minutes. If he is interested in filing any one digest, he will find it simple to tear out, and a convenient size to fit into any notebook.

It is a monthly periodical designed to meet the needs of every practising physician or teacher of medicine.

Each month the Editorial Staff combs over 200 medical journals to get the newest and proven material to be digested and put into easily read form for the practitioner. Each issue contains forty to forty-five digests.

Unbiased selection of current opinions concerning the newer drugs are a feature.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.(Eng.)

"It is almost unnecessary to say anything in recommendation of this well-known work, though it is a pleasure to record once again that it fully maintains the very high standard of its predecessors."—*Brit. Journal of Surgery.*

RECENTLY PUBLISHED. 212 *pp.* 10/- *net: postage* 6d.

TREATMENT OF SOME CHRONIC AND 'INCURABLE' DISEASES

By A. T. TODD, O.B.E., M.B.(Edin.), M.R.C.P.(Lond.).

A stimulating challenge to the traditional therapeutics, which, with years of inadequacy to support it, is content to accept the terms 'chronic' and 'incurable' as final.

"It shows so much both of ability and of enthusiasm, and its story of a long-sustained struggle with the cancer problem cannot escape our admiration."—*The Lancet.*

2nd Edition. Fully Revised. 158 *pages.* 50 *Illustrations.* 7s. 6d. *net; postage* 6d.

LATENT SYPHILIS AND THE AUTONOMIC NERVOUS SYSTEM

By GRIFFITH EVANS, M.A., D.M.(Oxon.), F.R.C.S., D.O.M.S.

"This volume is unquestionably a very important contribution to syphilology. The reviewer is convinced that if this second edition is carefully studied by all who are engaged in medical work a great deal of unsuspected syphilis will be uncovered, and with that much human suffering will be alleviated."—*Med Officer.*

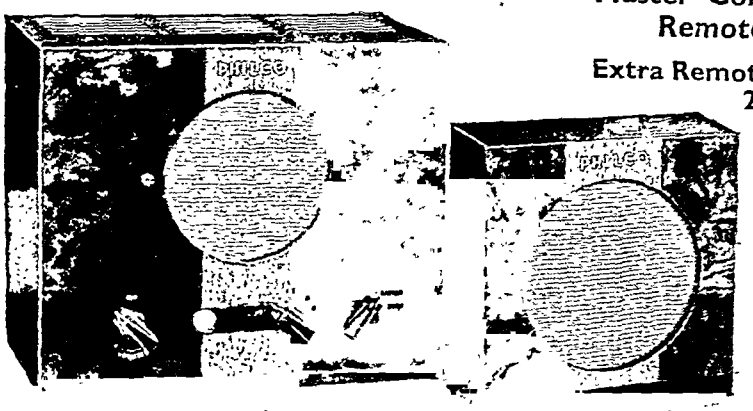
MEDICAL MEN are saving time and trouble with PHILCOPHONE



INTER-COMMUNICATION SYSTEM

—GIVES MORE—COSTS LESS

A Philcophone gives you private and immediate two-way communication between a Master Control Unit and one or more Remote Units in other rooms. Through the Master Control you can speak to all the Remote Units together or to each separately. The special Philco microphone-loudspeaker picks up your voice from any corner of the room, and relays it at whatever strength is desired.

No trouble to install. Housed in an attractive walnut cabinet. Sturdily built for long, reliable service. A knob controls the volume, and a red signal light shows when the system is in operation.

The Philcophone is one of the least expensive and the most convenient inter-room communication systems on the market. No rent to pay. No lease to sign. No complications. Write for full particulars today.

Master Control and one Remote Station

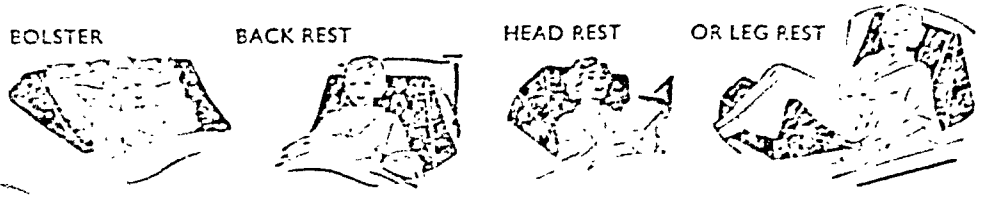
A BOLSTER *that becomes an Invalid Bed Cushion in a second!*



The Dunlopillo Adjustable Bed Cushion is invaluable to invalids and convalescents. In a second it can be converted from a bolster to a back rest, head rest or leg rest, providing an ideal support. It avoids using extra pillows, which are not really comfortable, and enables the patient to recline or sit up in bed in luxurious comfort. The soft resilience of the Dunlopillo Bed Cushion never needs punching up, it always keeps its shape. It is porous, self-ventilating, moth proof, dustless and completely hygienic.

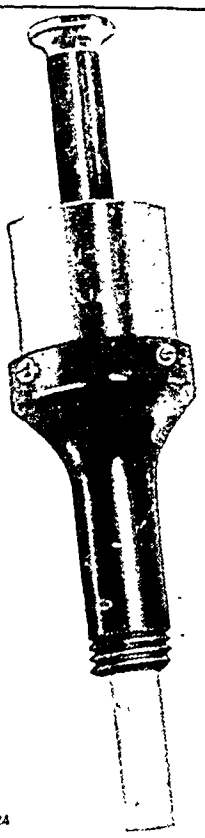
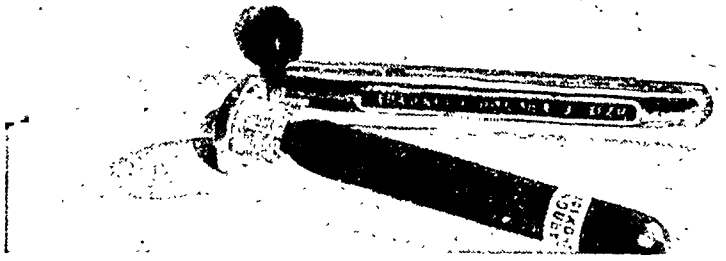
PETO-SCOTT
MAXADE

NEW MIDGET VALVE HEARING AID

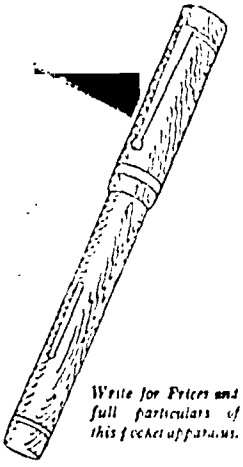


● The great service to the deafened of compensated valve amplification (*vide* Dr. A. W. G. Ewing, Mrs. J. R. Ewing and Dr. T. S. Littler, Privy Council Report, Series 219) is now available in Maxade Hearing Aids, with the additional advantages of variable compensation over the full range of speech frequencies, in an instrument as small and compact as scientific requirements and mechanical ingenuity will permit.

A variable "pitch" control permits the patient at all times to self-adjust the instrument to the individual degree of deafness—high, middle, or low. Interchangeable for either Air or Bone Conduction earpieces.



● MAXADE ELECTRICAL Hearing Aids will gladly be sent for free clinical test to any member of the medical profession.



Instruments for free clinical test and full information: please write to W. Scott-Worthington, Managing Director,

THE IDEAL ANTACID

Magnoleum is an emulsion of liquid paraffin and magnesium hydroxide prepared entirely by mechanical means without the aid of any constipating mucilaginous emulsifying agents. Its action is that of its active ingredients in an extremely fine state of sub-division. Being perfectly miscible with water or milk it may be diluted before taking, given to bottle-fed infants in food, etc. It is readily acceptable to children and delicate or fastidious adults.
Issued in convenient wide mouthed glass bottles, 1/3 and 2/6. Write for specimen for clinical trial.

KERFOOT

MAGNOLEUM STOMACH CORRECTIVE

Made in England by THOMAS KERFOOT & CO. LTD., Vale of Bardsley, Lancashire.

NUTRITIONAL NEEDS IN PREGNANCY

"Those who have followed the interesting experiment carried out in South Wales . . . in which the diet of expectant mothers has been very materially increased in regard to protein and the B group of vitamins among other supplements such as milk, must have been impressed with the results."
(Brit. Med. Journal., Aug. 7th, 1937, p. 259.)

Marmite is one of the few foodstuffs especially selected by medical experts for distribution to pregnant women in South Wales and other depressed areas, where the experiment referred to above is being conducted.

MARMITE

is an autolysed yeast extract rich in vitamin B_1 and vitamin B_2 complex

Practical Applications of the

KAYLENE-OL

Treatment

CHRONIC COLITIS

(Simple Mucous, Muco-Membranous, Post-Dysenteric).

(Kaylene Brand of Colloidal Kaolin with highly viscous liquid paraffin)

Alternating intervals of constipation and diarrhoea often occur in cases of colitis. Kaylene-ol is applicable in either phase. Its soothing and adsorptive actions combat the irritative diarrhoea, and its softening and lubricating actions counteract constipation during the intervals.

DOSE—KAYLENE-OL: 1 or 2 dessertspoonsful three times a day, half hour before meals, or in mild cases half hour before breakfast and at bedtime.

Kaylene-ol c̄ Phenolphthalein (0.5 per cent.) is taken when constipation is particularly troublesome. Dosage as for Kaylene-ol.

Samples and Literature from the sole manufacturers:

KAYLENE LIMITED, WATERLOO ROAD, LONDON, N.W.2.

Disorders of Digestion and Nutrition in Infants and Young Children

LUIZYM has been of inestimable value to us in suppressing the undoubted danger, particularly rife in summer, of digestive disorders due to an insufficiency of active enzymes. Luizym assists these enzymes and ferments in the disintegration of vegetable foods and also prevents excessive development of intestinal gases.
Waber: Cernauti Medical 1936, *No.* 7, *p.* 495.

With the aid of LUIZYM infants are able to take highly nutritious vegetable food without any fear of the dangerous disorders of digestion or nutrition that occur, particularly in the hot months, when such change of diet is made.

Samples and Literature sent on application.

MEDICAL LABORATORIES LTD.
40, PALL MALL, LONDON, S.W.1
Telephone: WHitehall 2486.

Method of use: One LUIZYM tablet to be given per 100 grm. of vegetable food. The powdered tablet should be stirred into the sieved vegetables.

In bottles of 20 and 50 tablets.

Valentine's Meat-Juice

IB 9-

ANTISEPSIS

The full development of Antisepsis demands an agent which, while efficient, does not damage human tissues, nor inhibit the normal function of the natural defences against infection. That Verpine is efficient has been proved during years of clinical trial. When used at fully antiseptic strengths Verpine has negligible effect on human tissues, while one of its active principles encourages natural resistance to infection by promoting leucocytosis, and is a protoplasmic stimulant. Verpine, moreover, is agreeable to use, and possesses a pleasant, refreshing odour.

VERPINE Regd. **ANTISEPTIC AND GERMICIDE**
NON-POISONOUS

Sample and literature gladly sent upon request.

'EUPINAL'

(IODIDE OF CAFFEINE)

Combining the therapeutic properties of caffeine and of the iodides in a specially elegant and effective form, "EUPINAL" is being increasingly adopted in cases of asthma, chronic bronchitis, and in affections of the cardiovascular system. It is free from toxicity, has no cumulative effect and is well tolerated even when prescribed over long periods. A fully descriptive booklet dealing with the Pharmacology, etc., of "Eupinal" is available upon request

MANDELIX

(*Elixir of Ammonium Mandelate B.D.H.*)

However impressive may be the results of laboratory investigations, it is in the exigencies of daily practice that the real test of clinical effectiveness of any new form of treatment is made.

Confirmatory evidence of the value of Mandelix in the treatment of urinary infections is forthcoming almost daily as a result of its regular use in the routine of general practice, the following clinical report being typical of many '... *patient suffered with chronic B. coli for* 15 *years; after one course of Mandelix the urine became sterile and has remained so for* 18 *months, catheter specimens being taken every* 3 *months.*'

Mandelix is supplied in bottles containing 7½ fluid ounces —sufficient for treatment lasting seven days.

Sample on request.

Mndx/S/39

Oral Vaccine for the prevention of Colds and Influenza

Since Genora brand Oral Vaccine was introduced to the Medical Profession last Winter, extensive clinical and laboratory tests have shown that it establishes a high degree of immunity against colds and influenza; the oral vaccine has also proved successful in the treatment of chronic bronchitis and similar respiratory infections.

This vaccine contains hæmolytic streptococci, in addition to other organisms incriminated in the causation of coryza and influenzal infections. It has been found that the ingestion of the oral vaccine against colds and influenza also develops immunity to diseases caused by hæmolytic streptococci.

Particulars concerning Genora brand Oral Vaccine will be found in the new brochure on Vaccine Therapy which has recently been published by Genatosan Ltd. This booklet also gives information regarding a wide range of vaccines administered by hypodermic injection and the standard types of Local Immunity Products. A copy of the brochure will gladly be supplied to any physician on request.

"*Proctocaine*" is a lasting, non-toxic, local anæsthetic, for use in irritating or painful conditions of the skin and subcutaneous tissues. It is an improved form of A.B.A. "Proctocaine" is a combination of oil-soluble anæsthetics of low toxicity. These are combined so as to produce *immediate local anæsthesia* which is maintained by the slow, uniform absorption of its oily vehicle, and action of its oil-soluble ingredients.

The advantages of "Proctocaine" over other solutions have been found[1] to be as follows:

1. Its effect is almost certain.
2. It produces anæsthesia or hypo-anæsthesia for periods varying from 7 to 28 days or longer.
3. The relaxation which it produces in the anal musculature is much greater and more prolonged.
4. It is comparatively non-toxic, injection of 20 to 30 c.cm. producing no general effect.
5. Even large quantities of it at one sitting have not been found to produce any local reaction if injected properly.
6. Its injection is painless if made slowly.
7. In no case did it produce severe after-pain.

SULPHONAMIDE-P B.D.H.

(*P*-aminobenzene sulphonamide)

For oral administration in hæmolytic streptococcal and other bactericidal infections

The efficacy of Sulphonamide-P B.D.H. in the treatment of puerperal septicæmia has been fully demonstrated and its value in other infections of hæmolytic streptococci is generally recognised.

Investigations indicate, further, that Sulphonamide-P B.D.H. may prove effective in infections due to other bacteria as, for example, meningococci and staphylococci.

Sulphonamide-P B.D.H. is issued for oral administration in tablets each containing 0.5 gramme of the pure substance, *p*-aminobenzene sulphonamide.

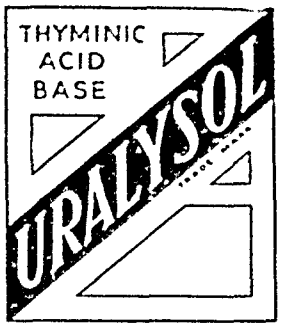
An accurately planned diet for the period 10 to 24 months

Follow-on Trufood

with feeding tables allowing for the progressive introduction of solids.

The new Trufood product, Follow-On Trufood, has met with a more than favourable response from the Medical and Nursing professions. It is recognised as logical that there should be an accurately-planned diet for the period 10 to 24 months, just as there is, in Humanised Trufood, for the period from birth to nine months. Follow-On Trufood is the bridge which carries the child safely over from the first stage of infancy to the stage where an adult diet can be taken.

Follow-On Trufood contains : Animal Proteins, Bone-marrow, emulsified Cream Fat, the soluble carbohydrates Lactose and Glucose, Mineral Salts, Organic Iron, Lecithin, Calcium, with Vitamins A, B_1, B_2 and D, from natural sources.



Complete feeding tables, giving full instructions for the progressive introduction of solids, are provided with each tin of Follow-On Trufood.

Further particulars and samples of Follow-On Trufood will be sent on request to :

TRUFOOD LIMITED
(DEPT. FBJ 17)
THE CREAMERIES
WRENBURY, CHESHIRE

TFF/4A/29

FORMULA

Thyminic Acid	0·10
Hexamethylenetetramine-Anhydromethylenecitrate	0·50
Hexamethylene Tetramine	2·50
Piperazine Tartrate ..	0·25
Lithium Carbonate ..	1·00
Sodium Benzoate ..	1·00
Effervescent Base ..	ad 100

DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

Uralysol, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

CONTINENTAL LABORATORIES LTD. **30 MARSHAM STREET, LONDON, S.W.1**

CONTRAMINE

(diethyl-ammonium-diethyl-dithiocarbamate)

Contramine is employed in the treatment of the chronic stage of disease, especially chronic complications of gonorrhoea such as stricture, chronic epididymitis, conjunctivitis and gonococcal arthritis.

Further, a course of Contramine will prevent (or ameliorate) metallic intoxication of any origin; it may be given with advantage, therefore, collaterally with arsenical preparations in cases in which the patient is found to be intolerant of arsphenamine and its substitutes.

It is in chronic rheumatism, however, whether of gonococcal origin or not that Contramine has been used with success. A physician reporting on his experience in the use of Contramine in a case of rheumatism which he suspected was subsequent to gonococcal infection stated that he had '. . . marvellous results, the rheumatism clearing up completely.'

THE BRITISH DRUG HOUSES LTD. LONDON N.1

Gluco-Fedrin

THE development of vehicles suitable for medicaments employed in the treatment of inflammation of the nasal mucosa has been the subject of special investigation. Studies in the Parke, Davis Laboratories have been undertaken with the specific purpose of finding a vehicle that is stable, non-irritating and miscible with the nasal secretion. Various oils and oily emulsions were discarded because, being immiscible, they tended to hinder or delay the action of medicaments. Aqueous solutions and glycerinated vehicles are not entirely free from irritating properties. An isotonic dextrose solution containing menthol, Chloretone and ephedrine was found to be superior to other preparations tested. Its blandness, ready miscibility with the nasal secretion, and stability make it particularly satisfactory. Such a combination is now available under the name "Gluco-Fedrin" and is suggested for use as a vaso-constrictor in diagnostic investigations of the nose and accessory sinuses as well as for the treatment of hayfever and other forms of allergic rhinitis.

FORMULA

Ephedrine	1 *per cent.*
Chloretone	0.5 *per cent.*
Menthol	0.1 *per cent.*
Dextrose Solution	*q.s.*

Supplied in 10 c.c. bottles, each with a dropper.

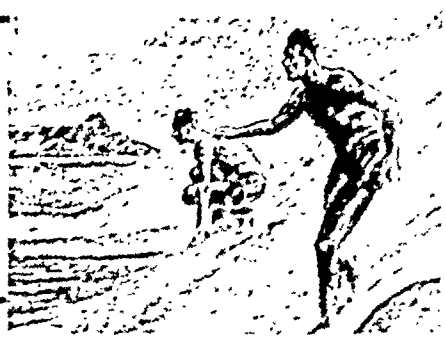
We Suggest that You Recommend

THE ORIGINAL PINEAPPLE JUICE FROM HAWAII



THIS appetising fruit juice from Hawaii offers a sparkling change from routine fruit juice menus. Children especially like it. Because it is assimilated so easily it is ideal for babies. That is why, when your patients ask your advice about fruit juices, we suggest that you recommend Dole—the *original* Hawaiian pineapple juice. This *delicious, golden juice is sealed in tins by the exclusive* Dole Fast-Seal Vacuum-Packing Process. That is why Dole Pineapple Juice retains, in high degree, the fresh-fruit constituents of ripe pineapple, as well as the fragrant, field-fresh flavour. Also it is a natural source of vitamins A, B, & C. J. K. Husband & Co., Ltd., 10 Eastcheap, London, E.C.3.

Here is a typical Analysis of Dole Pineapple Juice:

Moisture	85.3%
Ash	0.4
Fat (ether extract)	0.3
Protein (N × 6.25)	0.3
Crude fibre	0.02
Titratable acidity as citric acid	0.9
Reducing sugars as invert sugar	12.4
Carbohydrates other than sugars (by difference)	0.3

THE SURF RIDER.—Surfing, the sport of Hawaiian kings in olden days, was one of the favourite pastimes. Owing to the way the surf breaks on the reef, Waikiki is the only place in the world where this sport is indulged in under ideal conditions.

It is a fascinating sight to see the supple, bronze-skinned natives of the island paddle out on a surf-board, then stand on it as it comes in.

P.S. Just write to us on your letterhead and we will be pleased to send you a free sample tin of Dole Hawaiian Pineapple Juice.

"ALOCOL"

Colloidal Hydroxide of Aluminium

Effective in Nervous Dyspepsia

WHATEVER be the fundamental cause of nervous dyspepsia, it is acknowledged that alleviation of the gastric symptoms is an important part of effective treatment.

Nervous dyspepsia connotes hypersecretion. This causes flatulence, sour stomach, discomfort, and perhaps pain. 'Alocol' provides the ideal gastric sedative since its action is prompt and lasting and entirely free from harmful effects.

'Alocol' acts by adsorbing excess of free hydrochloric acid in the stomach, forming a colloidal jelly which passes through into the intestines and is finally evacuated. 'Alocol,' therefore, actually removes from the system the causative radicle (Cl) instead of merely temporarily neutralizing it. 'Alocol' does not interfere with normal digestion, nor does it determine any unpleasant secondary reactions. It is issued in tablet and powder form

FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research, acetyl-salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has, however, caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that "Alasil" definitely solves the problem of administering acetyl-salicylic acid in an effective form, being free from the risk of irritating the stomach or bowels or of causing general reactions.

A supply for clinical trial with full descriptive literature sent free on request.

In "Alasil" the desirable therapeutic effects of acetyl-salicylic acid are well exhibited by its calcium acetyl-salicylate moiety, while the presence of "Alocol" (*Colloidal Hydroxide of Aluminium*), a powerful gastric sedative and antacid, obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

M. tetragoni	25 ,,	
B. influenzæ	25 ,,	

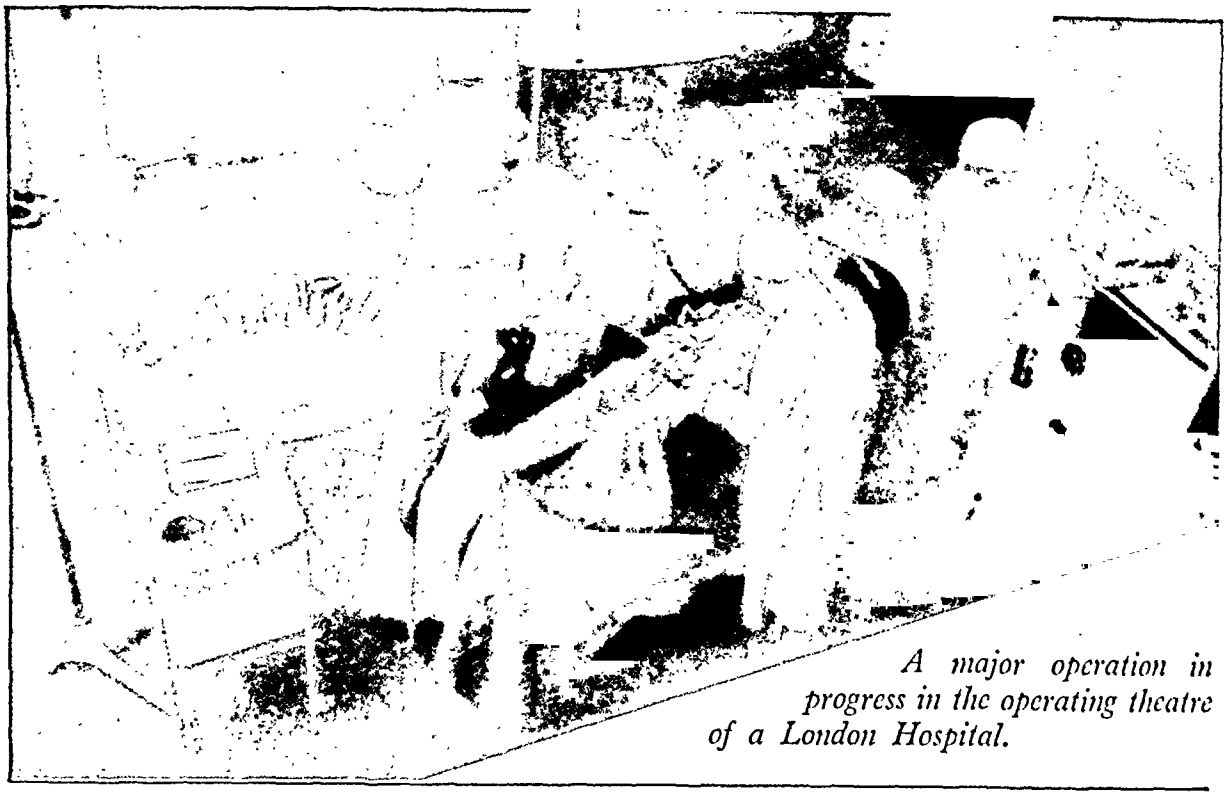
DOSAGE—PROPHYLACTIC (Vaccine No. 3)

As different patients vary in their reaction to vaccine treatment, it is only possible to suggest the average procedure. A brochure which deals fully with the question of dosage will be sent on application. In general, a series of three injections (given before the season during which the person is usually susceptible) is recommended. The initial dose is 0.25 cc. followed by 0.5 cc. after an interval of seven days, and a further 1 cc. after another week or so.

DOSAGE—CURATIVE (Vaccine No. 1)

In acute conditions an initial dose of 0.1 cc. or 0.2 cc. and in chronic conditions 0.25 cc. The initial dose may be repeated after three days. If no reaction is produced, subsequent injections can be larger.

EVANS' "COMMON COLD" AND ANTI-CATARRH VACCINES (Local Strains) are issued as follows:



Boxes of 3 × 1 cc. Ampoules, No. 3 Vaccine (Prophylaxis) .. 7/6 per box
Boxes of 6 × 1 cc. Ampoules, No. 1 Vaccine (Treatment) .. 14/- per box

Also in 5 cc., 10 cc. and 25 cc. bottles and in single Ampoules

Made in England at EVANS' BIOLOGICAL INSTITUTE by

Evans Sons Lescher & Webb Ltd.

Liverpool and London

A major operation in progress in the operating theatre of a London Hospital.

DEGREES OF PROTECTION....

THE most elaborate precautions against every possible chance of germ infection are of course essential in the operating theatre. It would be ridiculous, however, to expect anything approaching this meticulous attention to antiseptic cleanliness in everyday hygiene and in the home treatment of superficial wounds.

The general public is nevertheless beginning to realise the importance of germ-free cleanliness. Hygienic standards to-day are higher than they have ever been. It is generally agreed by medical men that although regular use of antiseptics is not desirable or really necessary for ordinary toilet purposes, the use of a reliable antiseptic soap can play a very valuable part in the prevention of infectious disease. Face and hands are continually exposed to infectious germs, and require washing with Wright's Coal Tar Soap.

Wright's has substantial antiseptic and antipruritic qualities. For over 70 years it has enjoyed the confidence of the medical profession, and to-day more doctors use Wright's than any other brand of toilet soap. Wright's Coal Tar Soap is prepared from materials selected after stringent tests. It is the only soap in the world to contain 'liquor carbonis detergens' (Wright's), the valuable dermatological therapeutic recommended by skin specialists the world over. In surgeries, hospitals, nursing homes and private households Wright's meets all the requirements of modern everyday hygiene. You can use it and recommend it to your patients with complete confidence.

THE HOUSEHOLD LARES WERE GUARDIANS OF THE ROMAN FAMILY, PRESERVING IT FROM SICKNESS AND OTHER ILLS. IF NEGLECTED, THEY COULD INFLICT DISEASE, USUALLY NEUROSIS AND PSYCHIC DISORDER.—The Lar familiaris was once unanimously considered the spirit of the mythical family ancestor, and in the plural, as the spirits of the subsequent ancestors. Some authorities now consider that the Lar represented the guardian spirit of the family's holding of land and was taken into the house and became the object of daily worship. The health of the whole household was believed to depend on due honour being paid to these gods who were held in great affection. The illustration shows a family shrine or Lararium. On the back wall is painted the Genius of the master of the house, with a Lar on either side, and on the altar slab in front stand images of deities including Apollo and Mercury, with a Lar at either end.

DATE: Throughout Pagan times. The shrine, c. 50 B.C.

The Common Cold

AUTUMN INJECTION CAN NOW CONFER WINTER IMMUNITY

Consistent evidence from clinical sources over the past four years shows that the new principles of vaccine therapy established by Dissolved Vaccine G.L. have brought to cold prophylaxis an assurance of majority success. The immunity response to the Cold Dissolved Vaccine G.L. is more consistent, more rapidly developed and of a higher degree because the total antigens are in solution and thus immediately available on injection.

Further, because the antigens are detoxicated, a full dose (½ to 1 c.c.) may be given from the first without fear of undesirable reaction. Three injections at intervals of a week should suffice. The rapidity with which immunity is developed enables prophylaxis of colds to be carried out at any time. It is advisable, however, particularly for patients known to suffer from recurrent winter colds, to administer the vaccine in the early autumn.

FOR TREATMENT Injection of the Cold Dissolved Vaccine G.L. has also achieved conspicuous success in treatment. One or two doses (½ to 1 c.c.) administered in the early stages of a cold will, in the majority of cases, bring about a rapid regression and termination of the symptoms.

LONDON SATURDAY SEPTEMBER 4 1937

EDUCATIONAL NUMBER, SESSION 1937-8

EDUCATION IN SURGERY FOR GENERAL PRACTICE

BY

SIR DAVID WILKIE, M.D., Ch.M., F.R.C.S.

Professor of Surgery, University of Edinburgh

At the present time there is a somewhat widespread feeling of discontent with the medical curriculum, and various plans are being discussed for its amendment and improvement. It is generally conceded that with the immense additions to knowledge in the last two decades, with the development and growth of specialties, and with the wealth of technical detail which each of these involves, the medical student of to-day tends to have brought before him more than he can assimilate, and is thus apt to lose balance and perspective. The need for a thorough grounding in the fundamental sciences has become more and not less necessary. The plea that all the earlier subjects in the curriculum should be vocational in their ambit loses sight of the fact that the medical course is essentially a training of the mind, not a technical course in practical methods for dealing with the sick.

Before considering the teaching of a subject such as surgery—how it should be taught, when it should be taught, and what should be taught—it is essential that we should have our object clearly in our minds. I believe I voice the general opinion when I describe the object of the medical course as the training of the mind of the student so that he can face any new problem or unusual situation, observe and assess the conditions, and deal with the problem—be it an individual patient, an outbreak of disease, or a question in preventive medicine—in a scientific, a rational, and a reasonable manner. The first two years of the curriculum have given the student the habit of thinking along scientific lines. It is eminently desirable that this habit be not broken when he is introduced to the study of patients in the wards. Thus the earlier teaching in both medicine and surgery should be devoted to those conditions which allow of accurate observation, logical deduction, and rational therapy. In the latter half of the curriculum teaching has become more difficult if more interesting, because it is the teacher's duty to sift out from the mass of accumulated knowledge the general principles and illustrate their application.

In the teaching of surgery to undergraduates we must first consider what should be taught, and then discuss the best ways and means of giving such teaching. To draw clearly demarcated boundaries between the provinces of the physician and surgeon in teaching is not only artificial, it is wrong. Our object is to educate rather than to instruct the student; the surgical ward may offer the best opportunities for education in medicine, just as the indications for surgery may become most evident in the wards of the physician. The greater the co-ordination and harmony of effort in teaching of the two great divisions of medicine, the more complete and generous will be the education of the student.

What Should be Taught

Complete agreement exists that surgical teaching must include the treatment of wounds and broken bones, of many deformities, of certain acute infections, of a considerable number of abdominal emergencies, of a variety of tumours and new growths, and of certain forms and stages of visceral disease. It is not only desirable but necessary that along with this teaching the practical aspects of anatomy, physiology, and pathology should be intimately correlated.

The methods of teaching available are lectures, tutorial classes, classes in applied anatomy and physiology, clinical bedside teaching, clerking in the wards, attendance at operations, work in the surgical out-patient department, and resident clinical clerkship in a hospital. Much criticism has been directed at the *didactic lecture* which at one time occupied the foremost place in surgical teaching. It is admitted that with the numerous textbooks now available the need for a long and complete course of lectures on surgery has gone. On the other hand I disagree entirely with those who belittle the value of the lecture and the spoken word. The function of the lecture is not to replace but to expound and annotate the textbook. If the lecturer can, from the multitude of facts, extract the essential ones which bring out a principle; if this principle can be expounded and its application illustrated from the lecturer's own experience; if thus the rational basis of surgical practice can be portrayed, the student will read his textbook with understanding and will be in a position to gain the greatest benefit from his work with patients in the wards.

After experience of several methods of presenting surgical lectures I believe that the best plan is to give an introductory course (say thirty to forty lectures) to students who have just finished their anatomy and physiology courses and are starting their clinical work. These lectures deal on broad lines with the surgery of wounds, infections, fractures, tumours, and, in the same manner, with the surgery of special regions and viscera. Such lectures form

part of a combined course with medicine, and are correlated with lectures on pathology, bacteriology, and pharmacology. At its best this system of correlated instruction during the student's third year has a broad educative value, not exceeded by any other part of the medical course. It has been our experience in Edinburgh that the students who shine in the co-ordinated examinations of this course almost without exception take the highest places in the final examination.

A second course of lectures on surgery may with advantage be given in the final years of study with this proviso —that the last three months before the final examination shall be left free of all lectures. In this course of senior lectures (fifty in number), which will follow regional lines, the lecturers on special branches of surgery should take their places, each being allotted by consent a certain number of hours. The applied anatomy, physiology, and pathology of each region will be dealt with as a preface to the surgical aspects. In this way interest in the earlier scientific subjects will be continued throughout the entire course.

Coincident with or immediately following the introductory course in surgery the student begins his work in the surgical wards. This may form the most valuable part of his training, or it may be more or less of a sinecure. Owing to the complicated character of many of our surgical procedures, and the smooth and aseptic healing of wounds, the student's opportunities of actually dressing wounds are very limited. The term "dresser" is now a misnomer and is disappearing. The great opportunities of the surgical wards are in diagnosis and in the acquirement of a clinical sense. If the students will examine the patient and discuss the clinical features, and, after all observations have been made and their significance debated, will come to a reasoned diagnosis, any operation on such a patient becomes a real and interesting lesson.

May I state here that the method of conducting a ward clinic on such a patient is important. In some respects it may be interesting and impressive that the surgeon should elicit the history, conduct the examination, and then by logical steps come to a diagnosis. In my experience this has little educative value for the student: only by active mental processes can he gain the education we desire. The duty of the teacher is to guide the student in eliciting information, conducting a physical examination, and coming to a final diagnosis. If the teacher does all the active thinking the student may be taught; he is not trained. The less a clinic approaches a lecture and the more it resembles a debate with many active minds participating, the greater its educative value.

Attendance at Operations

This brings us to the vexed question whether, as some hold, students are wasting time by attending operations. To spend hours watching from a distance intricate technical procedures is unquestionably waste of time for the undergraduate. On the other hand, to see displayed the living pathology of the condition, the diagnosis of which has been the subject of hot debate, is to learn a lesson which will be indelibly printed on the students' minds. The clerk of the case should be on the floor of the theatre, and should read his notes and then discuss the diagnostic features, coming finally to a fixed diagnosis. If this is confirmed at operation he gains in confidence and keenness; if it prove to be wrong the reasons for the error are discussed.

A considerable amount of applied anatomy can be taught at operations, and the lessons of accurate haemostasis, of minimizing trauma to the tissues, and of preventing all undue exposure and shock can be given by both precept and example. Particular stress must be laid on the attendance at emergency operations. This means that the student shall be in hospital on certain evenings when the majority of such operations are performed. The value of seeing the patient on admission, taking the history, making the physical examination, coming to a diagnosis, and then seeing the findings at operation and following the after-course, particularly if all steps are followed by discussion, cannot be overestimated.

While it is desirable that a senior student should know the essential steps of certain emergency operations, such as those for perforated duodenal ulcer, strangulated hernia, acute appendicitis, and ruptured ectopic gestation, it is not the operative technique or procedure so much as the correlation of symptoms and signs with living pathology that gives this experience its singular value.

Operative Surgery

In most medical schools a compulsory course on operative surgery on the cadaver, combined with applied anatomy, is given. The value of such a course is the training in handling a knife and doing the amputations and minor operations which any graduate might be called on to perform. The arguments against such a course are the scarcity of subjects, the dissimilarity between the lifeless tissues and the living body, and the relatively small amount of practice which the individual student gets in such a course. I believe that the course should not be dropped, but rather that it should be strengthened by co-ordinating it with the teaching of applied anatomy, and so giving the final brush up in this subject in the undergraduate course.

Post-operative Observation

The careful study of even a few patients after operation will give the student an insight into the troubles and the worries of the sick man and what can be done for them. He sees the distress of post-operative vomiting, and perhaps assists in washing out the stomach. If vomiting persists he notes the signs of dehydration and the remarkable relief given by fluid replacement by rectal, subcutaneous, or intravenous routes. If vomiting be absent the diet given to patients after various operations is studied in individual cases, the sedatives required, the doses and effects. He will learn how to deal with flatulence and with retention of urine. He may see develop before him a chest complication such as massive collapse of a lobe of one lung. If he witnesses the sudden distress and cyanosis, the rise in temperature and in pulse rate, and finds dullness with diminished breath sounds at one base and the heart pulled to that side, diagnoses a collapse, and sees the treatment carried out, he has had a life-long lesson in practical medicine. Or a patient develops a small pulmonary embolism and the student witnesses the symptoms, signs, and course of an infarct of the lung.

Another patient develops auricular fibrillation following operation, and the complete course and the response to treatment of this complication are got by first-hand study. Following on a peritonitis from a perforated peptic ulcer or appendicitis a patient develops a subphrenic abscess or a pleurisy with effusion going on to empyema: the whole clinical picture, with its constitutional and local features, evolves before the student's eyes.

The observation, study, and record, followed by discussion, of any of these post-operative troubles, providing

the facts are actively assimilated, digested, and understood by the student, gives not only a lasting knowledge of certain maladies but a method of approach and a habit of mind which can be applied with equal value to the solution of all other problems in practical medicine.

I have stressed the importance of post-operative observation because I believe that some of the most profitable studies of the early phases of certain acute medical diseases can be made in surgical wards.

Surgical Out-patient Department

The importance of attendance and practical work in the out-patient rooms is realized by both teachers and students. The treatment of minor wounds, of whitlows and cellulitis, of sprains, of fractures of the upper limb, and of various minor deformities so important to the man in general practice, is all carried out in the out-patient rooms. It is a serious handicap to our surgical teaching that in some of our larger schools it is impossible, owing to the number of students, for all to work in the out-patient rooms. Possibly when we get extended facilities for resident students this defect in our present system may be remedied.

Residence in Hospital

The most important advance in medical education which could take place would, in my opinion, be the provision of facilities whereby every student before graduation would be required to spend three months as a resident clinical clerk in a hospital. In the Irish medical schools this has become a valued tradition; in some British schools it is possible for a minority of students, and wherever it is possible its peculiar worth is indisputably recognized. It matters little whether the student is attached to medical or surgical wards, for he probably sees some of the work in both; the great gain is continuity of observation, a real personal interest in and responsibility for his patients, and the chance of acquiring practical experience in the clinical methods which later practice will demand.

It is impossible that all our young graduates can get resident hospital appointments. Apart from the relative paucity of the latter, considerations of finance compel many young graduates to plunge into practice. The value of a resident hospital appointment is patent and unquestioned. I consider that the greatest and most valuable benefaction to practical medicine in this country to-day would be the provision of resident accommodation at our great teaching hospitals and at a selected and approved number of provincial and municipal hospitals so that every graduate from our teaching schools would have that background and outlook which practical contact with accurate scientific clinical investigation alone can give. Research in medicine, possible for the very few, will never lack financial backing. Training those who man the outposts is just as important as the staff work at the base, for it brings scientific medicine to the homes of the people.

Special Branches of Surgery

Some branches of surgery are now recognized as specialties and, in large centres at least, are practised exclusively by specialists. It is eminently desirable that the student should have the best instruction in these branches, and the only difficulty is to keep a real balance and a proper perspective in such teaching. In respect of undergraduate instruction the nearer such branches are kept to the parent stem the better the education. While the intensive cultivation of a specialty unquestionably favours advance in knowledge it tends to prejudice perspective and make teaching lop-sided. The specialist is naturally impressed with the many points which his experience has shown to be of capital importance in his practice, both on the side of diagnosis and on that of treatment, and to him it seems only fair that the student should learn of these. The trouble is that the poor student's brain will not absorb and carry the multiplicity of important points which specialized experience has given during years of work.

It is thus imperative that instruction in the special subjects should be on the broadest lines, with a minimum of technical detail. What the student should be taught in each special subject is the method of investigation required to gain the most accurate data on which to found a diagnosis. In short, the student must be trained in how to acquire knowledge of disease, no matter which region or system is affected.

Surgery of the Ear, Nose, and Throat.—What systematic teaching is required in this subject might well be given by a specialist in this branch in the course of senior surgery lectures; to keep it in its true perspective the number of lectures should not be more than three, or at most four. The important part of the training in this branch should take place in the special out-patient department, where the student can examine patients and make himself familiar with the methods of investigating the ear, the nose, and the larynx. This practical training is of the first importance for general practice, and a certificate of proficiency in the simpler methods of examination should be required before the final examination.

Orthopaedic Surgery.—This specialty, which during the past two decades has become firmly established in this country, deals with lesions that are of great significance to the student and the practitioner: to the student because many of the lesions are readily visible and demonstrable and give great scope for developing powers of observation and accurate record: to the practitioner because so many deformities can be prevented or greatly lessened by timely recognition and treatment. Certain principles can be readily propounded and illustrated in clinical cases, and a few (two or three) lectures on general lines might be given in the junior surgical course. Attendance at an orthopaedic out-patient clinic should be compulsory. It is here that the student learns the rational application of splints and plaster-of-Paris, and by handling patients appreciates the necessity for systematic and thorough examination before coming to any decision as to the diagnosis and therapy. In the senior course of lectures on surgery six lectures on orthopaedics should be given by the lecturer on that subject. The custom of treating the majority of fractures in the orthopaedic dispensary or wards is now established in some teaching hospitals. Whatever views we may hold as to who should treat fractures, it will almost inevitably tend to become more and more the perquisite of the orthopaedist. The follow-up and rehabilitation departments attached to this unit should form a valuable training ground for the student. The handicap resulting from faulty alignment, the benefit from voluntary effort in restoring function, the various deformities and disabilities resulting from faulty treatment, and the ways in which they can be obviated and corrected, all these can be demonstrated in such a way as to leave a lasting imprint on the student mind. Attendance, on say eight occasions, at the orthopaedic ward or Cripples' Hospital, should be compulsory. Both offer splendid material for training, and most students are attracted by the visible and palpable lesions which come under review.

Neurological Surgery.—This, one of the youngest of our specialties, should be dealt with in the senior surgery lectures, say three lectures illustrated, if possible, by clinical cases. It goes without saying that the elaborate operations performed in this branch of surgery should not engage the student's attention. What should be taught are the broad principles governing cerebrospinal surgery and the various types of lesion which are amenable to operation.

Thoracic Surgery.—Up to now teaching in this subject has been done by general surgeons, and, whilst an occasional lecture from one of the men who have devoted themselves to developing this branch of surgery would be both interesting and instructive for students, a special series of lectures is not yet called for.

Urology.—In this country urology is still largely in the hands of the general surgeon, and is taught by him. Whether it will ever break off completely from general surgery is doubtful. The special accurate methods of coming to a clear diagnosis in this field are unequalled in any other branch of surgery. The student must see the diagnostic methods carried out and learn with what accuracy a lesion may be tracked down. I find that there are very few students who are not thoroughly familiar with all the modern methods of diagnosis in this specialty, which at the present time has the highest percentage of accurate pre-operative diagnoses of any branch of visceral surgery.

Anaesthesia.—The teaching of anaesthetics to students has been handicapped of recent years by the multiplicity of methods and of drugs that have come into use. In this essentially practical art lectures have comparatively little value. All students should give, under supervision, ether, gas and oxygen, and local anaesthesia. It is here that the student who is resident in hospital or is acting as an unqualified clinical assistant gains such valuable experience.

Radiotherapy.—In the treatment of malignant disease of the buccal cavity the surgeon has been largely replaced by the radiotherapist. As there is a tendency to segregate these cases for radium or *x*-ray therapy one must ensure that the student is kept in touch both with their diagnosis and with their treatment. At least two visits to the radiotherapy unit should be made by each student. In the course of senior lectures on surgery two lectures on radiotherapy, its possibilities and limitations, should be given by the specialist in that subject.

I have omitted to refer to venereal disease as it is now controlled and taught by members of what is almost a special branch of medicine. My only remark would be that, important as the subject and high as the standard of teaching undoubtedly are, this specialty must not be given an undue proportion of the student's time.

Conclusion

To sum up, the teaching of surgery offers great scope for training the student in accurate observation and in living pathology. Intensive study of a particular case is infinitely more important than learning the accumulated wisdom of others concerning the patient's disease. To acquire the habit of correlating clinical symptoms and signs with pathology is the essence of medical training, and surgery offers a fruitful field for this acquisition. The young graduate who starts in practice versed in the broad principles which surgical teaching supplies, trained in the methods of examination whereby facts may be disclosed and in the logical inferences that may be drawn from them, may know very little of operative technique and detail, but will have the essentials for successful and enlightened practice.

THE PROFESSION OF MEDICINE

In accordance with long-standing custom we preface the main contents of the annual Educational Number of the *British Medical Journal* with some remarks by way of guidance to those who contemplate entering the profession of medicine. What is said here will follow the lines laid down in previous years; but readers of each subsequent section should bear in mind that not only the methods of medical education but even its purpose are still under close scrutiny in responsible quarters.

THE STUDENT'S CURRICULUM

A revision of the medical curriculum has been under consideration for the last few years. Four important reports on medical education have been issued—the final report of the American Commission; the report of the British Medical Association's Committee; a Bulletin on "Medical Education and the Reform of Medical Studies" issued under the auspices of the Health Organization of the League of Nations; and the report of a Conference of Representatives of the Universities of Oxford, Cambridge, and London, the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. They may be said to be essentially at one as to the main points in which reform is required. So far as relates to the British position, there is common agreement that it is undesirable to lengthen the five years' medical course, but it is recognized that the course should be regarded as beginning at the time when the study of human anatomy and physiology is entered upon, and that this should be at approximately the age of 18 years—slightly later than is permitted under the present regulations. It is held, further, that a higher standard of general education than the present minimum should be required of those entering upon this course; that the requirements as to knowledge of the basic sciences of physics, chemistry, and biology should be modified and extended; that instruction in psychology, genetics, and methods of clinical examination should be introduced into the first two years of the curriculum; that the course should be regarded as a whole, with greater co-operation among the teachers of the several subjects, and not divided into segregated departments; and that, throughout, the preventive and psychological aspects of medicine, the living human personality in health, the sociological duties required from medical practitioners, should receive more prominent attention than has hitherto been common. At its meeting in May last year the General Medical Council passed new resolutions and recommendations carrying into effect the suggestions just enumerated. These are to come into force on November 1, 1938. Though the new pre-registration requirements will not apply in every respect to students entering on their studies before that date such students may well familiarize themselves with the changes which become operative before their period of study is completed. Moreover, parents of intending students should have in mind that

the pre-registration requirements bear upon the course of study in school between the ages of 16 and 18 years. It must be remembered that the powers of the General Medical Council are limited, and that quite as much depends upon the action of licensing bodies and medical school authorities as upon the Council. Indeed it may be said that, whatever regulations and minimum requirements are laid down, and however admirable are the arrangements set out in the prospectus of a university or teaching body, success depends upon the ability and inspiration of the teacher and an adequate response on the part of the student.

FINGER-POSTS

The first object of the Educational Number, 1937, as of all its predecessors, is to inform prospective students and their parents of the steps that must be taken in order to become a registered medical practitioner under the existing order of things. The second is to help those wishing to know what a medical career has to offer, and others who, having already decided to study medicine, are uncertain about the line of work for which they are best suited. This introductory article gives an opportunity of touching upon some aspects of medical study and practice, and of directing attention to a few points that might not occur to anyone without experience of the medical life.

Intending students will find in the pages that follow an account of the course of training required of them at the present time, the places where it can be obtained, and the bodies which test the knowledge gained and confer degrees or diplomas entitling successful candidates to become legally qualified medical practitioners. Sections are included also on postgraduate study, on the higher qualifications, and on most of the varied spheres of work, private or official, which are open to registered medical men and women at home and abroad. The details given are founded on official information, and arranged along the customary lines.

PORTALS OF THE PROFESSION

The *Medical Register* is the official statutory list of legally qualified medical practitioners kept by the General Medical Council. There are many ways in which admission can be obtained to the *Register*. No fewer than twenty-seven bodies—eighteen universities and nine corporations—either separately or jointly, issue registrable qualifications, and the number of teaching institutions is even larger. Nevertheless, the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same for all students. But the individual teaching and examining bodies have different standards and requirements and bestow different qualifications, and the choice should therefore be made early, so that a definite plan may be followed. The possession of a university degree is generally regarded as an advantage in practice, yet a considerable proportion of medical men in this country find themselves debarred from obtaining it because the Conjoint Examining Boards formed by the union of medical corporations have no power to grant degrees. The decision to study for a university degree in medicine should, if possible, be made by the time a boy or girl is 15. A matriculation examination or its equivalent should be attempted without delay, and the parent should ensure that the special requirements of the medical faculty of the selected university are fulfilled.

The conditions with which those who wish to enter the profession must comply are regulated by the General Medical Council, which is a statutory body set up under the Medical Acts; a summary of its functions and requirements is given at page 447. Every student, after passing examinations in the subjects of general education and in the preliminary sciences of chemistry and physics, must take a course of training at a recognized medical school, covering a period of at least five years, but usually extended to six years or more.

Examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain medical corporations in England, Scotland, and Ireland. The requirements of these licensing bodies are summarized elsewhere under separate headings. One of the functions of the General Medical Council, besides that of keeping the *Medical Register* and maintaining discipline within the profession, is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses at approved institutions. Successful candidates eventually receive either degrees, in the case of a university, or diplomas or licences, in the case of a corporation; these qualifications entitle them to claim insertion of their names on the *Medical Register*. Every student, as soon as he obtains his qualification to practise, should at once register; otherwise he cannot hold a public medical appointment, or sign any certificate required from a legally qualified practitioner (such as a death certificate), or recover professional fees in a court of law.

COST OF MEDICAL EDUCATION

This resolves itself into the cost of training at medical school and hospital, and the cost of living during the five or six years of undergraduate study. Besides differences in the charges made for instruction there are differences in examination fees, as well as in the fees for certificates of qualification, and those who seek the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. School and examination fees, together with the cost of board, lodging, clothes, travelling, and recreation, form the largest items, and to these must be added the money spent on books, microscope, instruments, and so forth.

Since professional education must continue for five years at least (a period exceeded by the vast majority), and since the cost of living varies much in different parts of the country, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession should be prepared for an outlay of at least £1,500. Something between two-thirds and three-quarters of the whole amount would probably be spent on maintenance, and the rest in fees for tuition, examinations, and admission to degrees or diplomas. For those who have to live in rooms away from relatives £120 per annum for board and lodging, etc., is probably a minimum figure. The fees charged by the different schools and licensing bodies are stated in the paragraphs relating to each on other pages of this issue. When making an estimate of the probable outlay, the many helps available nowadays for the reduction of expense should not be ignored. At nearly all the medical schools more scholarships and money prizes are offered now than in the past; at the Scottish universities bursaries are numerous; and the Carnegie Trust (whose regulations are summarized at page 459) gives pecuniary help to many Scottish students. The main thing to bear in mind when

considering costs is that, as compared with other professions, the period of training in medicine is long, and for most students expensive. Further guidance on this matter will be found in a memorandum[1] issued by the General Medical Council. This pamphlet gives much useful information, including a comparative table of the cost of study and examination at the various institutions.

NUMBERS OF STUDENTS AND DOCTORS

The following brief survey should be read with the notes and tables printed at page 446 on the numbers of registered students and practitioners. More new students mean more new doctors five or six years later, though there is a fairly constant wastage.

At the close of the last century the annual number of men and women who registered as medical students in the United Kingdom had been on the average about 1,800, and then for the next thirteen years it stood at about 1,400. During the war period, though many male students left to serve with the Forces, the entries grew steadily larger, so that in 1918 they were 2,253, and in the following year, when demobilization was in active progress, they reached 3,420. In the next five years the numbers rapidly fell, but from 1923 to 1928 they remained at a fairly steady level rather below the immediate pre-war average. In 1929 the entries rose again to 1,502, and in 1930 to 1,792. In the six following years they were 1,643, 1,947, 2,287, 2,350, 2,603, and 2,544.

In the past sixteen years the numbers of new practitioners registering each year have greatly exceeded the usual pre-war figure of eleven hundred or so. The large additions to the profession in recent times brought the total number of names on the *Medical Register* up to 59,010 at the end of 1936. This is about 6,400 more than the figure for 1926, 15,000 more than that for 1916, and 19,000 more than that for 1906. The population of the British Isles has not increased at anything like that rate during the same decennial periods, and the ratio of doctors to inhabitants is therefore much higher now than formerly. Some think that the saturation point has been reached, and that there is real risk of an overstocked profession. The numbers are certainly quite large enough. Of the total number of registered practitioners to-day some 10 per cent. are women; and, according to returns published by the University Grants Committee, women constituted 14.7 per cent. of the total full-time students of medicine and dentistry in England, Scotland, and Wales in the academic year 1935–6.

CHOICE OF CAREER

The months immediately after registration may be put to the greatest advantage by serving as house-physician, house-surgeon, or casualty officer in a hospital, by working as assistant or locumtenent in private practice, or by seeing something of the world as a ship surgeon. As a preliminary to practice of whatever kind, a year spent in junior appointments at a teaching hospital—"clinical experience under supervision"—is a most profitable investment.

Despite the apparent wealth of choice, the average newly qualified practitioner has to choose between private practice and an official or institutional career. Among the paths open are general medical practice, which absorbs three-quarters of all who qualify; Government service at home or abroad, including the medical branches of the Armed Forces; public health appointments and other administrative or official posts; institutional work, such as that of the municipal hospital (a rapidly widening field nowadays), the mental hospital, the fever hospital, and the sanatorium; academic positions in schools of medicine; general consulting practice as physician, surgeon, or obstetrician; and special work in scientific research or in one of the many subdivisions of clinical medicine and surgery. Most of these careers are discussed in some detail in later sections, but a few words may be said here about general practice and the work of a consultant or specialist.

Further information about such matters will be found in *The Medical Practitioners' Handbook*, published by the British Medical Association.[1] This comprises articles on openings for members of the profession; on practical aspects of medical work; on registration and the privileges of practitioners; on practice under the Insurance Acts; on specialization and special diplomas; and on medical defence societies. The appendixes include rules on the ethics of consultation, and a memorandum on the Dangerous Drugs Acts.

GENERAL PRACTICE

General practice, whether in town or country, is entered in one of three ways. The newcomer may take a house, put up a plate, and wait for work to come to him; he may buy the goodwill of a practice rendered vacant by retirement or death; or he may become a partner in an established firm. The first is more risky than the second, and the second than the third. A well-managed partnership of three or more has this advantage over single-handed practice, that it allows each partner leisure for recreation and for keeping up with the progress of medicine. Success in private practice demands a great deal of knowledge beyond that gained at the medical schools, and hence a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience as an assistant or deputy. Hints on how to begin general practice and on some of its pitfalls are given in a little book first published five years ago.[2] Another book recently issued, *An Introduction to General Practice*, will be of great value to senior students and the newly qualified.[3] This sets forth in clear terms a lofty ideal of what the general practitioner should aim at and how he should equip himself for the realization of that ideal in the day-to-day work of his profession.

Since three-quarters of those who pass out of the medical schools become "family doctors" sooner or later, it seems clear that the main purpose of the curriculum ought to be the training of the student for general practice.

"The general practitioner is the unit in the ever-growing complex machinery of health organization which modern civilization has made both necessary and possible, and the many specialized services, private and public, of hospitals, clinics, and health centres must depend ultimately on the co-operation of the general practitioner to fulfil their function in improving the health of the nation. Consequently there can be no more important need in medicine than a continued supply of efficient and well-trained general practitioners, and medical education can render the State no greater service than in making this object secure."

[2] *A Guide to General Practice.* By A. H. Douthwaite. H. K. Lewis and Co. (4s. 6d.)

[3] *An Introduction to General Practice.* By Sir Kaye Le Fleming. E. Arnold and Co. (5s.)

In its Proposals for a General Medical Service for the Nation[1] the British Medical Association states as an axiom that "the medical service of the community must be based on the provision for every individual of a general practitioner or family doctor"; and the whole series of proposals rests on this as a fundamental principle. In regard to the prevention of disease, on which the Association lays great stress in its memorandum, the general practitioner has an increasingly important part to play.

The national system of compulsory health insurance, now more than twenty-four years old, has had a profound influence on general medical practice in this country. On the whole the insurance system has proved of substantial benefit to medicine. By raising the standard of living among doctors it has induced a better class of man to enter the profession; and the service has steadily improved in efficiency. The Insurance Acts provide domiciliary medical attendance for some nineteen million persons, and more than 19,000 doctors undertake the medical care of this vast section of the community. Thus the bulk of the general practitioners of Great Britain now give, in large or small measure, attendance and treatment under a system embracing almost the whole working population. These practitioners, by placing their names on the panel (or medical list), signify their assent to the terms of service set out in the Medical Benefit Regulations and other relevant provisions. Their interests are watched over by the Insurance Acts Committee of the British Medical Association, which is the executive body of the Annual Conference of Representatives of Local Medical and Panel Committees.

CONSULTING PRACTICE: HIGHER DIPLOMAS

The term "consulting practice" comprises in ordinary usage the work of the general physician, that of the general surgical consultant or operating surgeon, and that of the gynaecologist and obstetrician. These are the three large divisions of consulting practice, as distinct from general practice, which, though they imply some restriction, yet call for a wide range of activity and outlook, in contrast with the smaller ambit of a "specialty" in the narrow sense. Of these main divisions the third is obviously the most limited, but on several grounds it can claim to rank as something more comprehensive than the other specialties. No sharp line can, however, be drawn between consulting practice and specialist practice. Most general consultants, whether medical or surgical, are specialists in some branch of their practice, and most specialists are consultants in the sense that their work largely comes to them through the recommendation of general practitioners, with whom they act (or should act) in a consultative capacity.

Specialism was a direct outcome of the growth and subdivision of the natural sciences and their application to medicine. It has proceeded apace during the present century, and it has had profound effects upon the practice and outlook of the individual surgeon and the individual physician, no less than upon the organization of hospital practice.

Success as a consulting physician or surgeon or specialist is hard to achieve, except by the aid of appointments to hospitals, particularly those with medical schools. These posts are much sought after, and the time of waiting for a vacancy may be long. It follows, then, that the would-be consultant, since he can scarcely hope at first to keep himself on his professional earnings, must either have private means or be prepared, by teaching or in other ways, to make ends meet. Competition in this branch of practice is very keen. Expenses are heavy, and the young consultant or specialist may have to go through a long period of training and waiting before he makes an income; but on the other hand success, when it comes, is liberally rewarded. In the larger industrial towns of the North of England there are many "general practitioner specialists" who combine ordinary panel practice with much surgical or other special work in well-equipped local hospitals which admit patients in different categories according to their means. Though the fees are small compared with those earned by operating surgeons and specialists in London, the work is by no means unremunerative.

Additional degrees and diplomas are important factors in securing election to the visiting staff of a large hospital, and a few remarks about them may be made here. Beyond the qualifications which admit to the *Medical Register*, most of the licensing bodies bestow higher titles after further tests. A considerable number of those who have graduated M.B. at a university, including many general practitioners, proceed later to the M.D. When applying for the post of physician to a hospital it is always useful, and may be obligatory, to hold also the Membership of one of the three Royal Colleges of Physicians, according to the part of the British Isles in which the hospital is situated. So, too, the Fellowship of one of the three Royal Colleges of Surgeons should be obtained by those seeking surgical appointments, and the degree of Master of Surgery is an added distinction. There are also diplomas in a growing number of special branches of work—such as public health, tropical medicine, ophthalmology, laryngology, radiology, tuberculosis, psychological medicine, midwifery, and anaesthesia—which are superfluous for most practitioners, but may be useful or even indispensable for those who intend to devote themselves to one or other of these subjects.

FINANCIAL AND SOCIAL ASPECTS

The course of training for the medical profession is long and expensive, and it may be some years after qualification before the practitioner can count upon an adequate return. For most private practitioners the working expenses are heavy in proportion to gross earnings. On the other hand, medical practice holds out the prospect of a fairly certain income, with unrivalled opportunities for exercise of the mind in the service of others. But those who think of adopting it as a career ought to understand that medicine is a path to fortune only for the few. Yet if from the financial point of view medical practice offers to most men little more than a means of livelihood, in its social and cultural aspects the outlook is far brighter. A doctor's life need yield to none in the matter of sustained and varied interest. His lot is unlike that of many whose business gives little scope to the higher faculties, for he lives in, and by, the exercise of intellectual powers. Gradual improvement in the education of the practitioner has added much to his influence with the public, and has been a large factor in raising his social status during the seventy-nine years that have passed since the General Medical Council was constituted under the first Medical Act. Medicine gives to those who follow it an honourable position. The well-educated doctor stands high among his neighbours, and is the friend and confidant of his patients. Many go further, and take part in the public life of their district; and this is as it should be, because the doctor's training and outlook are such as fit a man for leadership.

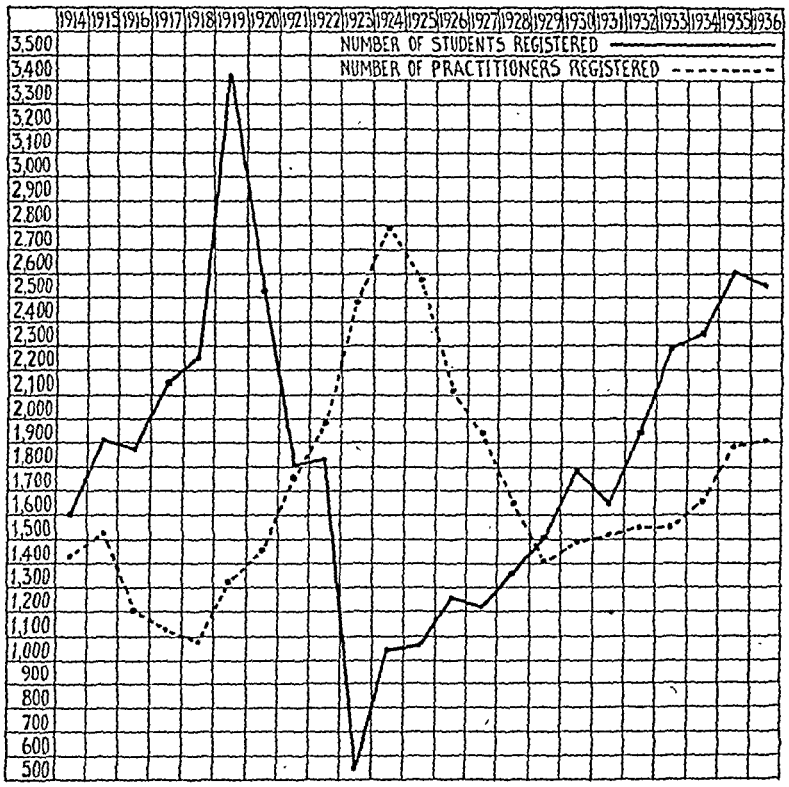
[1] The memorandum is issued as a pamphlet by the British Medical Association. (6d. post free.)

PROFESSIONAL ORGANIZATION

In no profession is a readiness to join hands for the common good more necessary than in medicine. Individuals and isolated groups are always at a disadvantage when they try to defend their interests against organized bodies, whether these are Government departments, local authorities, or commercial companies. In his daily work the competent doctor is well able to deal with the individual patient and the patient's friends, but he cannot stand up single-handed to outside organizations. Medical men and women must therefore band themselves together, and the first step after qualification should be to become a member of the British Medical Association. Besides having behind him the machinery and the influence of a world-wide professional body, a young practitioner will find in the meetings of his local Division, and in the Annual Meetings of the Association, many opportunities for keeping abreast of new work and for friendly intercourse with colleagues. Another thing that no new graduate should fail to do is to join one of the societies which for a small yearly sum undertake individual legal defence of their members. The need for protection may arise out of the first case attended in hospital or in private practice.

The British Medical Association was founded in 1832 to promote the medical sciences and maintain the honour and interests of the profession; a note on its constitution and activities will be found at page 512. This great Association, with Branches throughout the British Empire and a membership of 36,000, is the only body that can act for the profession as a whole and speak in its name. The record of a hundred years' work shows that vocational organization, wisely directed, can combine service for its members with service for the public. Every medical man and woman should try to take a share in some of the movements, scientific or social or political, with which the B.M.A. has identified itself.

NUMBERS OF THE PROFESSION



A Review of Fifty Years

In order to present a general view of the numerical strength of the medical profession during the past half-century we have extracted from the records and set down below in parallel columns the total number of names in the *Medical Register* on December 31 of each year, and the numbers added annually by registration between 1887 and 1936:

Numerical State of the "Medical Register"

Year	Names added in Year	Total No. on Dec. 31	Year	Names added in Year	Total No. on Dec. 31
1887	1,531	27,246	1912	1,157	41,439
1888	1,184	27,939	1913	1,168	41,940
1889	1,305	28,348	1914	1,433	42,378
1890	1,266	29,163	1915	1,526	43,225
1891	1,345	29,555	1916	1,202	43,481
1892	1,513	30,590	1917	1,134	43,819
1893	1,579	31,644	1918	1,077	43,926
1894	1,426	32,637	1919	1,322	44,510
1895	1,446	33,601	1920	1,457	44,761
1896	1,385	34,478	1921	1,760	45,408
1897	1,230	34,642	1922	1,983	46,476
1898	1,210	35,057	1923	2,482	48,140
1899	1,351	35,836	1924	2,796	50,035
1900	1,345	36,355	1925	2,570	51,738
1901	1,318	36,912	1926	2,120	52,614
1902	1,275	37,232	1927	1,941	53,769
1903	1,233	37,878	1928	1,656	54,336
1904	1,168	38,492	1929	1,410	54,870
1905	1,240	39,060	1930	1,490	55,291
1906	1,197	39,529	1931	1,522	55,604
1907	1,221	39,827	1932	1,546	56,097
1908	1,137	40,257	1933	1,542	56,741
1909	1,143	39,818	1934	1,664	57,496
1910	1,062	40,483	1935	1,882	58,361
1911	1,042	40,913	1936	1,905	59,010

Numbers of Medical Students and Practitioners Registering 1914 to 1936

The varying proportion of registered medical practitioners to population during the period under review is shown in the following table. This sets out the total population of the British Isles at each decennial census since 1881, and the number of names on the *Register* in the same year.

Proportion of Practitioners to Population

Year	Registered Practitioners	Population British Isles
1881	23,275	35,241,482
1891	29,555	38,104,975
1901	36,912	41,976,821
1911	40,913	45,370,530
1921	45,408	47,146,506
1931	55,604	48,989,485

These figures show a steady increase in the ratio of doctors to population, which was accelerated during the years immediately following the war. Making allowance for the large number of registered practitioners living abroad and for those no longer in practice, the proportion of doctors to population is a good deal more than one to every thousand.

Registration of Students and Practitioners

The relation between the numbers of new students and those of newly qualified practitioners during recent years is shown in the chart on this page, compiled from returns published by the General Medical Council.

Some further remarks on the numbers of medical students in recent years will be found in our introductory article on the profession of medicine.

The chart shows that the number of practitioners registering in any one year corresponds more or less closely to the number of students registered five years previously, the difference being accounted for by examinations and other obstacles. For the last ten years there has been a fairly steady annual increase in the numbers of both students and practitioners becoming registered. This gradual increase seems likely to continue.

The General Medical Council

The General Medical Council was established by the Medical Act, 1858, in order "that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." Eighteen members of the Council are appointed by the Universities in the United Kingdom having medical faculties; nine by the Medical Corporations, such as the Royal Colleges of Physicians and Surgeons; five by His Majesty in Council; and seven members are directly elected by members of the profession as a whole—a total of thirty-nine. To these are added three dentists who are members of the Dental Board, and are appointed for dental business. Although the eighteen members appointed by the universities and the five members appointed by His Majesty in Council may all be laymen, only two laymen have so far been appointed; the first of these was appointed by the Privy Council in 1926, and, on his resignation in 1931, another was appointed in his place. Both were members of His Majesty's Privy Council.

The Council's offices are at 44, Hallam Street, Portland Place, London, W.1, and there are Branch Offices at 44, Queen Street, Edinburgh, 2, and 35, Dawson Street, Dublin.

The Council exists for the protection of the public and not of the profession. Its principal functions are three. First, to keep the *Medical Register;* second, to see that the name of no person is entered thereon as qualified unless he has had an adequate professional education, and to remove therefrom the names of qualified persons who are no longer entitled to public confidence; and third, to provide for the publication of the *British Pharmacopoeia.* It is the appearance of a name upon the *Medical Register,* and not the possession of a degree or diploma, that constitutes a person a "duly qualified" or "legally qualified" practitioner of medicine.

The Council has no power to make rules in regard to the medical curriculum or examinations, but it can pass resolutions and make recommendations relating thereto, and if any of these were ignored by the licensing bodies, it would be open to the Council to make representations to the Privy Council, which, if it thought fit, might order that the qualifications obtained from such bodies should not be registrable.

The name of any medical practitioner who has been convicted of felony or misdemeanour, or who is judged, after due inquiry before the Council itself, to have been guilty of "infamous conduct in any professional respect," may be erased from the *Medical Register.*

The Medical Acts prohibit attempts being made to impose restriction as to any theory of medicine or surgery, and, once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any "theory" of medicine or surgery in which he honestly believes. The Medical Acts do not prohibit the practice of medicine by unregistered persons, but if they "wilfully and falsely" assume any title implying registration they are liable to prosecution. In this respect the Medical Acts differ from the Midwives and the Dentists Acts, which entirely preclude the practice of midwifery or dentistry by unregistered persons. Unregistered medical practitioners, however, are under certain disabilities, for they cannot recover charges for medical or surgical attendance, etc., in a court of law; they cannot hold an appointment as medical officer of health, in public (including mental) hospitals, or as a medical officer in the Military or Naval Services, or in ships; they cannot give any valid certificate which is required by any Act from a medical practitioner—for example, a certificate of death; and they cannot engage in insurance practice, obtain dangerous drugs, or attend cases of venereal disease.

An account of the recommendations which the Council has drawn up in respect of the education of medical students here follows.

Registration of Medical Students

The Council recommends that every intending student of medicine should be registered as such at one of its three offices, whose addresses are given on page 448.

Candidates must produce evidence (*a*) that they have attained the age of 17 years; (*b*) that they have passed an approved examination in general education; and that in addition thereto they have passed an examination in elementary chemistry and elementary physics conducted or recognized by one of the licensing bodies.

Application for registration should be addressed to the Registrar for the Division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained from any of the offices of the General Medical Council itself, or from one of the various licensing bodies or medical schools.

The regulations with regard to registration apply alike to medical and to dental students, with the exception that for dental students pupilage with a registered dental practitioner may be regarded as the beginning of professional study, and that applications for registration should be addressed to the London office of the Council only.

Professional Education *

The rule is that it is only from the date which appears against his name in the *Students' Register* that the medical student's career officially begins; thereafter five academic years at least must pass before he can present himself for the final examination for any diploma entitling its lawful possessor to registration as a qualified medical practitioner under the Medical Acts. But to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona-fide study; and in every course the following subjects should be included:

(i) Elements of General Biology, including an introduction to Embryology. This course, if the licensing bodies permit, may be taken before registration, and the examination may be passed immediately after registration.

(ii) Chemistry, Physics, and Biology in their application to Medicine.

(iii) Human Anatomy and Physiology, including Histology, Elements of Embryology, Biochemistry, and Biophysics.

(iv) Elementary Bacteriology, before regular clinical appointments.

(v) Pathology, general, special, and clinical, and Morbid Anatomy.

(vi) Pharmacology and Materia Medica, to be taken concurrently with clinical instruction.

(vii) Forensic Medicine, Hygiene, and Public Health.

(viii) Medicine, including Applied Anatomy and Physiology, Clinical Pathology and Therapeutics, Children's Diseases, Acute Infectious Diseases, Tuberculosis, Mental Diseases, Skin Diseases, and Vaccination.

(ix) Surgery, including Applied Anatomy and Physiology and Clinical Pathology, Anaesthetics, Diseases of the Eye, Ear, Throat, and Nose, Radiology, Venereal Diseases, and Orthopaedics.

(x) Midwifery and Diseases of Women, including ante-natal conditions and infant hygiene.

The Council recommends that during the last three of the five academic years clinical subjects shall be studied.

The first two years must be passed at a university, or at a school of medicine recognized by any of the licensing bodies, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body.

*New Resolutions in Regard to Professional Education were adopted by the Council on May 29, 1936, and will come into operation on November 1, 1938.

Special Considerations

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order:

(1) Pass an approved examination in general education;

(2) Pass an examination conducted or recognized by a licensing body in elementary physics and elementary chemistry;

(3) Having attained the age of 17, enter himself at a university or at a medical school recognized by one of the licensing bodies;

(4) Obtain registration as a medical student;

(5) Study for a minimum of five years certain prescribed subjects;

(6) Meanwhile pass sundry intermediate examinations; and at the end of the fifth year pass a "qualifying examination" which will entitle him to receive from a licensing body a qualification enabling him to obtain registration in the *Medical Register*, whereby he receives legal authority to practise.

The Minimum Period.—It must be remembered that the period of five years is a minimum; more is often required, even by the man of good abilities and reasonable industry, and some of the universities prescribe a longer period. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Thus, for instance, before presenting himself for any examination he must be "signed up" for the subjects covered by that examination; this means that his teachers have to certify that he has diligently attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place, he may miss enough of them to make it impossible for him to be signed up. Then again, should he fail to satisfy the examiners at some examination, he cannot present himself for re-examination for at least three months. This generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by the need for restudying the subjects in which he has failed, the Examining Boards usually insist upon a definite interval elapsing between one examination and the next. Further, many Boards have refused to recognize lectures and classes which have been attended before the student has passed the requisite examination in earlier subjects, and the Council now recommends that the professional examinations in anatomy and physiology be passed before the minimum period of three years' subsequent study be entered on; in other words, no clinical study should count as such until these examinations have been successfully completed. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the beginning of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a fact, the majority of students take longer.

In speaking of the minimum period, it is to be remembered also that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or the Diplomas of the Royal Colleges. Those who wish to take a higher qualification—for instance, the F.R.C.S.Eng.—must prolong their work for another year or more. So, too, in some cases, must those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended when he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

Memorandum on Students' Registration

The following memorandum has been drawn up on behalf of the General Medical Council as to the procedure for those who desire to be registered as medical or dental students.

The requirements for the registration of medical and dental students are the same, and every intending student should, in his own interest, register as soon as he begins his professional curriculum.

A recognized examination in general education must first be passed. If the student intends to obtain a university degree, he should apply to the university he selects for information as to its matriculation requirements in arts or pure science, or as to any examinations which may be accepted in fulfilment thereof. If the student intends to obtain a qualification from one of the licensing corporations (these are the Conjoint Boards in England, Scotland, and Ireland, the Society of Apothecaries of London, and the Apothecaries' Hall of Dublin), any of the examinations indicated below will be accepted. The subjects required are: (1) English, (2) Mathematics (elementary), (3) a language other than English, and (4) a fourth subject as required by the regulations of the particular examination, to be chosen from the following—namely, History, Geography, Botany, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by a university for matriculation. School certificates (other than "Higher") must show "Credits" in each of the prescribed subjects. When school certificates with four credits are presented, or certificates from the Educational Institute of Scotland and College of Preceptors, the passes in the four subjects must be shown to have been obtained at not more than two sittings.

The requirements of the preliminary examination in general education being satisfied, it is then necessary for the student to pass a further or pre-registration examination (theoretical and practical) in elementary chemistry and elementary physics, which is conducted or recognized by one of the licensing bodies—that is, a university or licensing corporation. These subjects must be passed *in addition* to those included in the preliminary examination—for example, chemistry, taken as one of the four required subjects in the preliminary examination cannot also count as one of the subjects of the pre-registration examination. These subjects may be studied at a university or medical school, or at a secondary school or other institution recognized by the body whose pre-registration examination it is intended to take. The student should, in every case, write beforehand to the body whose qualification he desires to obtain (a list will be found below) for information in regard to its requirements for this examination, and, although it is not necessary to pass in biology before registration as a student, application should be made at the same time to the body selected to ascertain their requirements in regard to this subject.

These two examinations (in general education and in physics and chemistry) having been passed, and the student having attained the age of 17 years, he should apply to one of the universities or one of the medical schools for admission to its course of medical study. When medical study has been begun, he should apply to the Dean of the School, or to the Registrar of one of the branches of the General Medical Council, for a form of application for registration as a student, and should have it completed and sent in to one of the Branch Councils as soon as possible. There is no fee for this registration. The medical curriculum will extend for at least five years, and the dental curriculum for at least four years, from the date of registration as a student.

A dental student may begin his curriculum, if he so desires, as a pupil in dental mechanics of a registered dental practitioner; but study at a dental school is to be preferred. If, however, he is apprenticed to a dental practitioner he will have to devote twice as much time to instruction in dental mechanics as he would if he had taken this subject in a school. This will have the effect of lengthening the curriculum. In any case a student can only obtain a concession of twelve months out of the four years' curriculum in respect of such apprenticeship.

The addresses of the Branch Registrars are:

General Medical Council, 44, Hallam Street, Portland Place, London, W.1.

Scottish Branch Council, 44, Queen Street, Edinburgh, 2.

Irish Branch Council, 35, Dawson Street, Dublin.

EXAMINING BODIES IN PRELIMINARY EDUCATION

The following is a list of the officials of the examining bodies in preliminary education, with the names of the examinations in parentheses:

Secretary, Queen's University of Belfast. (Matriculation.) Assistant Secretary, Ministry of Education, Belfast. (Senior Certificate.)

Registrar, The University, Bristol. (Matriculation, School Certificate, or Higher School Certificate.)

Registrary, The University, Cambridge. (Previous.)

Secretary, Cambridge Local Examinations, Syndicate Buildings, Cambridge. (School or Higher School Certificate.)

Medical Registrar, University of Dublin (Trinity College), Dublin. (Entrance examination to the School of Physic.)

Registrar, University of Durham College of Medicine, Newcastle-on-Tyne. (Matriculation, School or Higher School Certificate.)

Registrar, Irish Conjoint Board, Royal College of Surgeons, Dublin. (Preliminary Examination.)

Registrar, National University of Ireland, Dublin. (Matriculation.)

The Assistant Commissioner of the Department of Education, 1, Hume Street, Dublin. (Senior Grade Examination or Leaving Certificate.)

Secretary of the Examinations Council, The University of London, London, W.C.1. (Matriculation, General, or Higher School Certificate.)

Secretary, Northern Universities Joint Matriculation Board, 315, Oxford Road, Manchester. (Matriculation, School, or Higher School Certificate.)

Registrar, University Registry, Oxford. (Responsions.)

Secretary, Oxford and Cambridge Schools Examination Board, Schools Examination Office, Balliol College, Oxford. (School or Higher School Certificate.)

Secretary, Oxford Local Examinations, University Press, Oxford. (School or Higher School Certificate.)

Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1. (Senior Certificate at Credit Standard.)

Secretary, Educational Institute of Scotland 47, Moray Place, Edinburgh. (Preliminary Medical Certificate.)

Secretary, Scottish Education Department, 14, Queen Street, Edinburgh. (Leaving Certificate.)

Secretary, Scottish Universities Entrance Board, 81, North Street, St. Andrews. (Scottish Universities Preliminary Examination.)

Registrar, University of Wales, Cathays Park, Cardiff. (Matriculation.)

Clerk, Central Welsh Board, Cardiff. (School or Higher School Certificate.)

[*Note.*—Certificates of the College of Preceptors and School Certificates (other than "Higher") must show "Credits" in each of the prescribed subjects.]

LICENSING BODIES

The following is a list of officials of licensing bodies and their addresses:

ABERDEEN. The Secretary of the Medical Faculty, The University.

BELFAST. The Secretary, Queen's University.

BIRMINGHAM. The Registrar, The University.

BRISTOL. The Registrar, The University.

CAMBRIDGE. The Registrary, The University.

DUBLIN. The Medical Registrar, The University, Trinity College, The Registrar, National University of Ireland.

DURHAM. The Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne.

EDINBURGH. The Dean of the Faculty of Medicine, The University.

GLASGOW. The Registrar, The University, W.2.

LEEDS. The Registrar, The University.

LIVERPOOL. The Registrar, The University.

LONDON. The Academic Registrar, The University, W.C.1.

MANCHESTER. The Registrar, Victoria University.

OXFORD. The Dean, Department of Medicine, The University.

ST. ANDREWS. The Secretary, The University.

SHEFFIELD. The Registrar, The University.

WALES. The Registrar, The University Registry, Cathays Park, Cardiff.

LICENSING CORPORATIONS

ENGLISH CONJOINT BOARD. The Secretary, 8, Queen Square, Bloomsbury, W.C.1.

SCOTTISH CONJOINT BOARD. The Secretary, 18, Nicolson Street, Edinburgh.

IRISH CONJOINT BOARD. The Secretary, Royal College of Surgeons in Ireland, Dublin.

APOTHECARIES' SOCIETY OF LONDON. The Registrar, Blackfriars, London, E.C.4.

APOTHECARIES' HALL OF IRELAND. The Registrar, 95, Merrion Square, Dublin.

MEDICAL SCHOOLS

The following is a list of medical schools (other than universities) and their officials:

ABERYSTWYTH. The Registrar, University College. (University of Wales. First year only.)

BANGOR. The Registrar, University College. (University of Wales. First year only.)

CARDIFF. The Dean of the Medical School, Welsh National School of Medicine.
The Registrar, University College of South Wales and Monmouthshire.

CORK. The Registrar, University College.

DURHAM. The Registrar, College of Medicine, Newcastle-upon-Tyne.

DUBLIN. The Medical Registrar, University of Dublin, Trinity College.
The Registrar, University College.
The Secretary, School of Medicine, Royal College of Surgeons.

EDINBURGH. The Dean, School of Medicine of the Royal Colleges, Surgeons' Hall.

GALWAY. The Registrar, University College.

GLASGOW. The Dean, St. Mungo's College.
The Dean, The Anderson College of Medicine.
The Mistress, Queen Margaret College, W.2 (for women students of the University of Glasgow).

LONDON. Charing Cross Hospital, The Dean of the Medical School, W.C.2.
Guy's Hospital, The Dean of the Medical School, S.E.1.
King's College, The Dean of the Medical Science Faculty, Strand, W.C.2.
King's College Hospital, The Dean of the Medical School, S.E.5.
London Hospital, The Dean of the Medical College, E.1.
London (Royal Free Hospital) School of Medicine for Women, The Dean, 8, Hunter Street, W.C.1.
Middlesex Hospital, The Dean of the Medical School, W.1.
St. Bartholomew's Hospital, The Dean of the Medical College, E.C.1.
St. George's Hospital, The Dean of the Medical School, S.W.1.
St. Mary's Hospital, The Dean of the Medical School, W.2.
St. Thomas's Hospital, The Dean of the Medical School, S.E.1.
University College Hospital, The Dean of the Medical School, W.C.1.
Westminster Hospital, The Dean of the Medical School, S.W.1.

SWANSEA. The Registrar, University College. (University of Wales. First year only.)

This section of the Educational Number would be incomplete without brief mention of the memorandum drawn up on behalf of the General Medical Council on the procedure to be adopted by those who desire to enter the profession of medicine, to which reference is made in the introductory article at page 442. The pamphlet (price 1s. post free) sets out in plain language the information for which the Council is often asked by prospective medical students or their guardians.

Universities in England and Wales

There are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties.

UNIVERSITY OF OXFORD

Though the Oxford Faculty is the oldest in the kingdom systematic university teaching for students of medicine only really began in 1883, when Burdon-Sanderson came to Oxford from University College, London, to be the first Waynflete Professor of Physiology. From that date onwards there was a steady increase in the provisions for teaching and for the conduct of original investigation; the rate of this increase has in the last two years been accelerated—first, by the opening of the Nuffield Institute for Medical Research, and, secondly, by Lord Nuffield's munificent further gift of £2,000,000 to the University for the benefit of the Medical School. The first appointments under the scheme have already been made, and in the next few years the facilities for teaching and research, both in the preclinical and in the clinical departments of the school, will be considerably strengthened. On the other hand it is perhaps necessary to emphasize two points. In the first place Oxford does not wish to in-

crease the number of its medical students, but to keep up their standard of quality. In the second place it is not the intention of those who are planning the future that the average student should complete his clinical work in Oxford; possibly a few who are engaged in research may be given this opportunity when the Nuffield scheme is fully developed.

The courses leading to the medical and surgical degrees of the University (B.M., B.Ch.; D.M.; M.Ch.), as also that for the diploma in ophthalmology (D.O.), are open to both sexes. Whereas, however, a student must be a member of the University and have taken the degree of B.A. before he can take the medical and surgical degrees, these restrictions do not apply to candidates for the diploma in ophthalmology.

Guidance for Medical Students

At school, apart from acquiring knowledge, the prospective medical student should train himself to think clearly and to write clearly; he is also well advised to learn those languages, in particular German, which will be of use to him in his future reading.

Before he can become a member of the University, and thereby of the Medical School, a student has to be accepted by a college or by one of the non-collegiate bodies. This normally involves the taking of a college entrance examination, but exemption may be gained on the result of a college scholarship examination or in other ways. Correspondence on such matters should be addressed to the Head of the college concerned, and not to the Dean of the Medical School.

When a student has been accepted by a college he next has to pass, or obtain exemption from, the University entrance examination, Responsions; Latin is a compulsory subject in this or the exempting examination. Entries for Responsions or claims for exemption should be made through the Head of the student's college.

After passing Responsions or the equivalent the medical student normally takes the preliminary examinations in physics and chemistry and in biology. These he can attempt, if his school authorities are willing, before he comes into residence, and it is an advantage to him so to do, provided such a course does not interfere with his general education. These particular examinations satisfy simultaneously the preliminary requirements both of the University in respect of the B.A. degree in animal physiology and also of the General Medical Council in respect of medical qualification. Questions about alternative courses, and about entry for or exemption from these examinations, should be addressed by the student to the authorities of his college, and not to the Dean of the Medical School.

The first step taken after this is usually the passing of the examination in organic chemistry for First B.M. Exemption can only be claimed by those who have passed certain examinations in chemistry of the University. A man who has passed the preliminary examinations before coming into residence normally takes organic chemistry in his first term, and thereafter prepares for the examinations in human anatomy and physiology for First B.M., which he will probably take in his sixth term, though there are alternative courses. He must pass simultaneously in both anatomy and physiology, unless he has previously been placed in the first or second class in the Final Honours School of Animal Physiology, in which case he is exempted from the physiology part of First B.M. Nothing else can exempt him from the examination in this subject, and there is no exemption at all from that in human anatomy.

Practically every medical student attempts to obtain the B.A. degree by taking the Final Honours School of Animal Physiology, for this course diverts him least from purely professional work, and passing the preliminary examinations mentioned above allows him to enter for this final examination. The special course in preparation for it lasts one year, and the examination may not be taken earlier than the eighth term of residence unless the student has special status. If he enters for the examination later than his twelfth term of residence he is over standing for honours.

The student who has passed his preliminary examinations before coming into residence should thus have passed the examinations for First B.M. and for the degree of B.A. by the end of his third year at the University.

He must thereafter prepare for the examinations for Second B.M. The subjects are materia medica and pharmacology, pathology, forensic medicine and public health, medicine, surgery, and midwifery. The examinations in the first three of these can be taken separately, as soon as the necessary conditions are fulfilled, or simultaneously with any of the other Second B.M. examinations; on the other hand, a student must pass simultaneously in the three last subjects. The examination in these may not be taken, unless the candidate is already a registered medical practitioner, until the eighteenth term from matriculation and the lapse of at least thirty-three months from the date of passing the examinations for First B.M.

The whole of the work for Second B.M. may be done in recognized institutions away from Oxford—for example, the London medical schools. Alternatively, a student who has the necessary qualifications may spend the first six months in Oxford, and thereafter do a further twenty-seven months' work elsewhere. In this second case the courses which he will take at Oxford will last from September to the following March, and will include instruction in pharmacology, general pathology, and elementary medicine and surgery.

Further details about the course for the qualifying degree of B.M., B.Ch., and also about the higher medical and surgical degrees, are to be found in the current edition of *University of Oxford Examination Statutes* and in a pamphlet entitled "Information Concerning the School of Medicine, etc.," both of which can be obtained from the Clarendon Press, Oxford. College authorities, and the Dean of the Medical School, University Museum, Oxford, will also give any assistance that is within their power.

College entrance scholarships, open to would-be medical students, are advertised each July in a special number of the *University Gazette*, which can be bought for a few pence through any bookseller. In addition many valuable prizes, scholarships, and fellowships are awarded to medical students and graduates; they include the Radcliffe Travelling Fellowship, the oldest of such endowments for postgraduate travel and study, which is awarded annually, after examination, by the Master and Fellows of University College. Details about these prizes, etc., can be found in the current edition of the *Oxford University Calendar*.

It is very difficult to give an estimate of the expense of that part of the course which is passed in Oxford, as the cost varies very much with the different colleges. Eighty pounds a term is perhaps the amount paid by the average student, but many manage on less than this. Once the B.A. degree has been taken university and college dues are less.

UNIVERSITY OF CAMBRIDGE

The professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Chir.) (these degrees cannot be taken separately), and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants a diploma in medical radiology and electrology to medical practitioners, not necessarily graduates of the university. Information regarding this diploma will be found in a later section under the heading "Radiology." A candidate for the M.B., B.Chir. degrees must have passed the Previous Examination or some other examination accepted by the university as its equivalent under the new regulations. He must reach an honours standard in a Tripos. Naturally, most students will take the Natural Sciences Tripos, which qualifies him for the degree of B.A. The attainment of a sufficient standard in certain subjects in this Tripos will secure exemption from the corresponding tests in the M.B. course. Members of Girton College and Newnham College are admitted to the examinations.

Professional Examinations

An explanation of the changes in the medical curriculum at Cambridge, which came into force in October, 1934, was given in the *British Medical Journal* of July 7, 1934 (p. 26). To obtain the M.B., B.Chir. degrees candidates must have reached an honours standard in a Tripos and passed the First and Final Medical Examination.

First M.B.—This comprises (1) general and inorganic chemistry, (2) physics, (3) elementary biology, (4) organic chemistry. The parts may be taken together or separately. In either case the candidate, before admission to examination, must have passed or been exempted from the Previous Examination. Certain exemptions from the First M.B. Examination are allowed; the regulations may be obtained from the

Registrary. An examination in each part is held three times in the year.

A candidate for the Final Examination must have (*a*) completed the First Examination; (*b*) dissected the whole body adequately and thoroughly; (*c*) attended an approved course, and passed an examination in Pharmacology; (*d*) attained the honours standard in some Tripos; (*e*) attended an approved course, and passed an examination in anatomy and (*f*) in physiology.

Final M.B.—This is divided into two parts, to neither of which the candidate is admitted until he has fulfilled the conditions previously mentioned. A candidate for the first part, which deals with the principles and practice of surgery (including special pathology) and midwifery and diseases peculiar to women, must have completed five years of medical study and be signed up in these subjects, and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study, and be duly signed up in all subjects and have completed three years of hospital practice. The examination is in the principles and practice of physic (including diseases of children, mental diseases, and medical jurisprudence), pathology (including hygiene and preventive medicine), and pharmacology (including therapeutics and toxicology). The Final M.B. examinations are held twice a year—in June and December.

The Higher Degrees

The M.D. degree may be taken by a graduate of the University of eight years' standing who has passed the Final M.B. Examination, after writing a thesis approved by the M.D. Degree Committee, and keeping a further Act. He may also be allowed or required to take an examination, oral or written, or both, on the field of Medicine within which the subject of his thesis falls.

A candidate for the M.Chir. degree who is an M.A. may be admitted to the examination after he has become legally qualified to practise surgery. Other candidates may be admitted when two years have elapsed after they have completed the requirements for the B.Chir. degree, and may be admitted to the M.Chir. degree after three years have elapsed since they were admitted to the B.Chir. degree. The examination comprises pathology, surgery, surgical anatomy, and surgical operations. The tests are partly in writing, partly oral, and partly practical: they include the writing of an extempore essay. The examination is held in February in each year.

FEES

In addition to college fees, tutorial fees, and the expense of living, the following examination fees are payable: First M.B., £5 5s.; tests in Pharmacology, Physiology, and Anatomy, £1 1s.; Final Examination, £12 12s. For schedules referring to the examinations, list of schools and hospitals recognized by the university, and other information, application should be made to the University Registrary, Cambridge.

UNIVERSITY OF LONDON

Under the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Bachelor of Surgery, Master of Surgery in four branches, Doctor of Medicine in six different Branches, Bachelor of Dental Surgery, and Bachelor of Pharmacy. The university has its own matriculation examination, and it is most advisable that candidates should obtain and carefully study the booklets relating to it. The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days; the first two take place both in London and in certain provincial centres; the September examination is held in London only.

In no circumstances is a degree granted to anyone in less than three years after the date at which he passed the matriculation examination or obtained registration in some other way. All medical students must normally spend not less than five and a half years in professional study subsequent to matriculation, of which the last three years must be spent at a school of advanced medical studies.

Professional Examinations

M.B., B.S.—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination (held in July and December) covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order.

The Second Examination is held in March and July. Part I covers organic chemistry, the candidate's knowledge being tested as in the earlier examination. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in pharmacology may sit for re-examination in that subject alone if the examiners think fit, and candidates who pass in pharmacology only may similarly be credited with that subject.

No candidate, unless he is already a registered medical practitioner, is admitted to the Third M.B., B.S. Examination within thirty-three months of the date of his passing the Second Examination in Anatomy and Physiology. The subjects are medicine (including mental diseases), pathology, forensic medicine and hygiene, surgery, and obstetrics and gynaecology. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and obstetrics and gynaecology. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates, who have passed both groups of the examination at one time, are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination. A supplementary list is issued of candidates who have passed in one group only.

The Higher Degrees

M.D.—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S. unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) hygiene, (6) tropical medicine, and if he wishes, may pass also in another branch at a subsequent examination.

Two years must elapse between acquiring the M.B., B.S. and sitting for the M.D. in any branch, except that in the case of Branches I–IV a candidate who has obtained honours at the M.B., B.S. Examination may enter for the M.D. Examination after one year. Candidates may also be admitted to the M.D. Examination (Branches I–VI) one year after taking the M.B., B.S. examination on the grounds of exceptional experience in their subject. Certificates of approved appointments are required for the M.D. (Branches I–IV) except in the case of candidates who have been engaged in professional practice for five years. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of Branch IV, pathology in Branch I—an essay on one of two suggested topics with the special subject, and a clinical or other practical test. Both written and practical examinations must be passed, though exemption can be obtained from the former in exceptional circumstances. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

M.S.—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are four branches in which it may be obtained—general surgery, dental surgery, ophthalmology, and laryngology, otology, and rhinology.

FEES

For Matriculation: 2½ guineas for each entry. First Examination: 6 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination, Part I: 3 guineas for the first and each subsequent entry. Second Examination, Part II: 9 guineas for each entry to the whole examination. For re-examination in Pharmacology the fee is 4 guineas. For re-examination in Anatomy and Physiology the fee is 6 guineas. M.B., B.S.

Examination: 12 guineas for each entry to the whole examination, and 6 guineas for examination or re-examination in either group. M.D. and M.S. Examinations: 20 guineas, and 10 guineas on re-examination.

Inquiries should be addressed to the Academic Registrar, the University of London, W.C.1.

UNIVERSITY OF BIRMINGHAM

This university confers medical and surgical degrees—namely, M.B., Ch.B., M.D., Ch.M., and M.D. (State Medicine)—also degrees in dentistry (B.D.S. and M.D.S.), and Diplomas in Dentistry (L.D.S.) and in Public Health (D.P.H.). A degree of Ph.D. is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university. The M.B., Ch.B. candidate may also take in the earlier part of his medical curriculum courses leading to the ordinary B.Sc. degree in anatomy and physiology, or B.Sc. with honours. The extra time required for either of these science degrees is one year. The full course of study for the degrees of M.B., Ch.B. extends over six years. The Senate has power to accept courses of study and examinations passed at other recognized universities as exempting from the examinations in physics, chemistry, biology, and organic chemistry. In the case of such students at least three years must be spent in attendance upon classes at the university.

Students entering the Medical Faculty for the M.B., Ch.B. degrees must have passed—

(1) Either (*a*) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham; or (*b*) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are required to have passed in English literature and mathematics, and are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315, Oxford Road, Manchester. *Note.—In and after October, 1938, revised entrance requirements will come into force.*

(2) A recognized pre-registration examination in the subjects of chemistry, physics, and biology—for example, the higher school certificate of the Joint Matriculation Board; or a candidate may attend first-year courses in the university, October to June (chemistry, physics, and biology)—that is, First M.B., Ch.B. This examination may be passed in two sections; not less than two subjects must be passed on first entry.

Professional Examinations

The candidate for the M.B., Ch.B. degrees has four examinations to pass subsequent to passing the First M.B., Ch.B. Examination or exemption therefrom. In the Second (Part II) and Final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M.B. deals with physics, chemistry, and biology (pre-registration). The Second M.B. (Part I) comprises the subject of organic chemistry. The Second M.B. (Part II) comprises anatomy and physiology, and the student must pass in both simultaneously. The Third M.B. comprises pathology and bacteriology taken as one complete subject. The Fourth M.B. takes place at the end of the fifth year, the subjects being forensic medicine, toxicology, public health, and therapeutics (inclusive of pharmacology and materia medica).

Final M.B.—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a post-mortem clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, children's diseases, venereal diseases, ear and throat and skin diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners at the time of his examination a short written commentary on a gynaecological subject or case investigated during the period of gynaecological clerking. *Revised regulations for First-year and Second-year Courses and Examinations will come into operation in October, 1938.*

M.D.—An ordinary candidate for this degree must be an M.B., Ch.B. of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as holders of the Birmingham M.B., Ch.B.

The degree of M.D. (State Medicine) is open to M.B., Ch.B. graduates of the university who possess also a diploma in public health or degree in sanitary science or public health recognized by the university. The period of postgraduate study for this degree must occupy one year in the case of Birmingham M.B., Ch.B. graduates, and two years in the case of graduates of other universities.

The degree of Ph.D. is open to qualified medical practitioners under special conditions applicable in the Faculty of Medicine. Under these regulations the necessary attendance and research during a period of two years may be carried out in the laboratories of the university or in associated hospitals.

FEES

The fee for Matriculation is £2 (payable to the Joint Matriculation Board); £2 10s. for First M.B. Examination (if taken in university), and £2 10s. for each of the first four Professional Examinations; M.B., Ch.B. degree fee, £10; M.D. and Ch.M. Examinations, £12 10s. each. For further particulars application should be made to the Registrar or the Dean of the Medical Faculty, University of Birmingham, Edmund Street.

UNIVERSITY OF BRISTOL

In the Faculty of Medicine the following degrees are conferred: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: diploma in public health (D.P.H.),[1] diploma in dental surgery (L.D.S.), and diploma in veterinary State medicine. All candidates for degrees in medicine, surgery, and dentistry are required to reach matriculation standard in the school certificate examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates must be not less than 21 years of age and have pursued the courses prescribed by university regulations during not less than five years after passing the First Examination in chemistry and physics, and entry upon professional study at a medical school, of which three shall have been spent in the university, and two of these three subsequent to passing the Second Examination. All candidates for the degrees of M.B., Ch.B. are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: chemistry, physics, and biology. This part of the curriculum shall extend over one year. (Candidates who have passed an equivalent higher school certificate examination in these subjects will not be required to sit for the First Examination, and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: anatomy, physiology, elementary pharmacology, and elementary pathology.

The Final Examination.—The subjects of examination are: materia medica and pharmacy, pharmacology, pharmacotherapeutics and toxicology, pathology and bacteriology, (Section I); forensic medicine, public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical and operative, including ophthalmology and oto-rhino-laryngology), medicine (systematic, clinical, and practical, including mental diseases) (Section II). The subjects included in Section II may be taken in two groups—namely, Group I: surgery and obstetrics; Group II: medicine, public health, and forensic medicine. Candidates may pass Sections I and II together or separately, and the two groups of Section II may

[1] At present in abeyance.

likewise be taken together or separately, but no student can obtain honours who elects to take the two groups of Section II separately.

Degree of Doctor of Medicine.—Candidates must be Bachelors of the university of not less than two years' standing as such, and may elect either (1) to pass an examination in general medicine, or (2) to pass an examination in State medicine, or (3) to present a dissertation. The candidate who elects to pass the examination in State medicine must hold a diploma in public health of some university or college, and the candidate who elects to present a dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—The degree may be taken in general surgery or in special subjects. Candidates shall be Bachelors of the university who have practised for two years in an approved hospital (including the holding of an approved appointment for six months), and one of the two years shall have been spent in a hospital with a medical school attached. They shall present a dissertation and pass an examination. For general surgery, the examination shall include a written examination in surgery, a written examination in surgical anatomy and surgical pathology, a clinical examination, an oral examination, and an examination in operative surgery. For special subjects—that is, ophthalmology or oto-rhino-laryngology or gynaecology—the examination shall include a written examination in the anatomy, physiology, and pathology of the region of the body concerned (including in the case of ophthalmology, physiological optics), and a written examination in general surgery, together with a written, oral, and clinical examination in the particular branch of surgery concerned, as well as an examination in operative surgery of the region concerned.

UNIVERSITY OF DURHAM

To its own undergraduates, who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M.B., B.S.), and also grants the higher degrees of Doctor of Medicine (M.D.), Master of Surgery and Doctor of Surgery (M.S. and D.Ch.), Bachelor of Hygiene, Doctor of Hygiene (B.Hy. and D.Hy.), and Bachelor of Dental Surgery and Master of Dental Surgery (B.D.S. and M.D.S.); it also grants diplomas in public health, psychiatry, and dental surgery. The university accepts the Durham University school certificate examination (if a sufficient standard is obtained in certain specified subjects) for matriculation purposes, but also accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application. In addition to satisfying the matriculation requirements of the university, every student must (1) pass a pre-registration examination in physics and inorganic chemistry conducted or recognized by the university, and (2) be registered on the books of the General Medical Council. The university requires that at least three years be spent in residence in the university; in certain cases candidates may obtain exemption from the First and Second Examinations, but the later professional examinations must be passed in the university.

Professional Examinations

There are four professional examinations for the M.B., B.S. degrees. The First Examination is held in March, June, and December; the Second and Third Examinations in March and June; and the Final Examination in June and December. The first deals with biology and chemistry in relation to medicine; the second with anatomy and physiology; the third with pathology, bacteriology, materia medica, pharmacology and [illegible] l jurisprudence, and public health. At [illegible] he candidate is examined *in medicine*, and clinical medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical midwifery and gynaecology; and clinically in psychological medicine, diseases of the throat, nose and ear, diseases of the skin, diseases of the eye, and diseases of children.

M.D.—This degree is only open to Bachelors of Medicine of the university. They must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the Medical School, King's College, Newcastle-upon-Tyne (formerly the University of Durham College of Medicine).

M.S.—Candidates for this degree must have been engaged in practice for at least two years subsequent to qualifying M.B., B.S.Durham. The subjects of the examination are surgery, systematic and clinical, surgical anatomy and pathology, and surgical operations.

D.Ch.—The university grants also the degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 25 years of age. They must devote three years, subsequent to obtaining a registrable qualification, to the study of surgery and ancillary subjects; one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of Faculty of Medicine.

One year must be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as a resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

The Degree of Bachelor of Hygiene and the D.P.H.

A period of not less than two years must elapse between the attainment by a candidate of a registrable degree or qualification in medicine, surgery, and midwifery and his admission to the final examination for the degree of B.Hy or for the D.P.H. of the University as the case may be. The curriculum extends over a period of not less than twelve calendar months (or an academic year of whole-time study covering a period of not less than nine calendar months) subsequent to the attainment of a registrable degree or qualification. Candidates for the B.Hy. must take out the curriculum for Part I of the examination at the University of Durham, but for the D.P.H. may do so either at the university or at any medical school or institution recognized by the university. The examination is divided into two parts. Part I is practical, written, and oral, and includes the subjects of bacteriology and parasitology (including immunology, serology, medical entomology, etc.) especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; chemistry, physics, radiology, and electrology in relation to public health; physiology and biochemistry in their application to nutrition and hygiene; and meteorology and climatology in relation to public health. The subjects in Part II include the principles of public health and sanitation; epidemiology and infectious diseases; vital statistics; sanitary law and administration (including public medical services); sanitary construction and planning; and public health administration. This part of the examination is written and oral, and includes practical examinations in infectious diseases; food inspection; inspection of premises, dwelling-houses, factories, workshops, schools, etc.

Candidates are not admitted to examination in either part until after they have completed the prescribed courses of instruction in the required subjects.

Doctor of Hygiene

Candidates for the degree of Doctor of Hygiene must be Bachelors of Hygiene of the university of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of public health.

Diploma in Psychiatry

Candidates must be registered medical practitioners, and, unless qualified before January 1, 1911, must have attended, subsequent to passing their qualifying examinations, courses of instruction in (*a*) anatomy; (*b*) physiology; (*c*) pathology; (*d*) bacteriology; (*e*) psychology and experimental psychology; (*f*) clinical neurology; (*g*) psychiatry; (*h*) clinical psychiatry. The examination consists of two parts, namely: (1) anatomy, physiology, pathology, and bacteriology; (2) psychology and experimental psychology, neurology, and psychiatry (systematic and clinical); and candidates may present themselves for the whole examination or for either part separately.

FEES

The following fees are payable: Matriculation, £2; Examinations, Pre-registration, £3 3s.; First, Second, and Third M.B., B.S., each £5; Final M.B., B.S., £15; M.D. and M.S., each £5; B.Hy. and D.P.H., £12 12s., D.Psy., £10 10s., and D.Hy. and D.Ch., each £20; First, Second, and Third L.D.S., each £3 10s., and Final L.D.S. £5; First, Second, and Third B.D.S., each £5. Final B.D.S., £8; and M.D.S. £5. For degrees

and diplomas: M.B., B.S., B.Hy., and B.D.S., each £6 6s. *plus* the sum of 10s. if it is the initial degree taken in the university; M.S. and M.D.S., each £6 6s.; M.D., D.Ch., and D.Hy., each £10; D.P.H., D.Psy., and L.D.S., each £3.

Further information may be obtained from the Dean, Medical School, King's College, Northumberland Road, Newcastle-upon-Tyne.

UNIVERSITY OF LEEDS

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, in psychological medicine, in dental surgery, and in nursing.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in:

I. *Either* English Composition and English Literature, *or* English Composition and History.
II. *Either* Mathematics or Latin.
III., IV., V. *Three* other subjects not already taken under I and II above, chosen from the following list:

(1) English literature; (2) History; (3) Geography; (4) Greek; (5) Latin; (6) French; (7) German; (8) Some one other language approved by the Board; (9) Mathematics; (10) Mechanics; (11) Physics; (12) Chemistry; (13) General experimental science; (14) Natural history; (15) Botany.

Provided that (*a*) candidates who take Mathematics under II above must include one of the subjects 4–8; (*b*) candidates who take Latin under II above must include one of the subjects 9–15. Except in cases specially approved by the Senate candidates are required to present evidence of possessing a knowledge of mathematics at least equivalent to that of the "Pass" standard at a School Certificate Examination.

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

Professional Examinations

The examination for the M.B., Ch.B. number three.

The First Examination.—This consists of four parts (1) physics and inorganic chemistry, (2) organic and physical chemistry, (3) botany, (4) zoology, each of which may be taken separately, but candidates are not permitted to start their second year's work until Parts 1, 2, and 3 have been passed.

The Second Examination.—This consists of Part I, materia medica and practical pharmacy. Part II, anatomy and physiology. Candidates will be allowed to pass each part separately.

The Final Examination.—The Final Examination consists of Part I, pharmacology and pathology and bacteriology; Part II, medicine, surgery, obstetrics and gynaecology; Part III, forensic medicine, public health, and therapeutics. Part I may be taken at the end of the second clinical year, and must be passed before Parts II and III are taken. Parts II and III may be taken at the end of the third clinical year but not before the completion of the fifth year of medical study. If taken separately Part III may not be passed before Part II.

M.D.—Candidates for this degree must be bachelors of medicine and bachelors of surgery of the university, and subsequently to having graduated must have completed two years of hospital practice or special study approved by the university; or four years in the practice of their profession in one or other of its various branches; six months' hospital practice or special study to count as the equivalent of one year's ordinary practice. Any subject of the medical curriculum except surgery may be chosen for the examination, but a thesis, the title of which must previously receive the approval of the Board of the Faculty of Medicine, may be submitted, and if it is adjudged to be of exceptional merit the candidate may be exempted from further examination.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on ophthalmology and one on pathology and bacteriology; he is then examined in surgery in all its branches and in ophthalmology and pathology and bacteriology.

FEES

The Matriculation fee is £2, and on readmission £2 or £2 2s. 6d; for each of the other examinations £6 and £6 on readmission.

The fees for the M.D. and Ch.M. degrees are each £10 and the same on readmission. The fee for conferment of each of these degrees is £5.

UNIVERSITY OF LIVERPOOL

This university, besides granting degrees in medicine and surgery (M.B., Ch.B., M.D., Ch.M., M.Ch.Orth.), awards degrees in dental surgery and in veterinary science. Diplomas are awarded in tropical medicine (D.T.M.), tropical hygiene (D.T.H.), public health (D.P.H.), medical radiology and electrology (D.M.R.E.); also in dental surgery and in veterinary hygiene. The degree of Doctor of Philosophy (Ph.D.) may also be taken in the Faculty of Medicine.

Matriculation

The matriculation examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, 13, which accepts, under certain conditions, the tests of several other bodies as its equivalent. Candidates will be required to have included mathematics among the subjects in which they have passed at such examination. Revised conditions of entry upon degree courses will become operative as from December, 1937.

Professional Examinations

Candidates for the M.B., Ch. B. degrees have three examinations to pass, the first including (1) chemistry, (2) biology (zoology and botany), (3) physics.

Second M.B.—This covers (1) anatomy, (2) physiology, including biochemistry and histology.

Final M.B.—The subjects of the Final Examination are: Part I—(*a*) pathology; (*b*) pharmacology and general therapeutics. Part II—(*a*) forensic medicine and toxicology; (*b*) public health. Part III—(*a*) obstetrics and gynaecology; (*b*) surgery, systematic, clinical, operative and practical, including ophthalmology; (*c*) medicine, systematic and clinical, including therapeutics, mental diseases, and diseases of children. Candidates may take Parts I, II, and III separately, provided that candidates may not present themselves for Part III until they have completed the sixth year of medical study and have passed the examinations in Parts I and II.

M.D.—May be conferred on graduates (M.B., Ch.B.Liverpool): (i) on candidates of two years' standing. Such candidates shall be required to present a thesis certified to be the candidate's own work, together with copies of published original papers upon Medical Science (if the candidate desires). The thesis shall embody the results of personal observations or original research either in some branch of medicine or in some science directly relative to medicine. If the thesis is accepted by Faculty after report from the assessors, the candidate shall present himself for an oral examination on the subject of the thesis; (ii) on candidates of five years' standing by examination in (*a*) medicine and (*b*) a selected branch of medicine.

Ch.M.—May be conferred on graduates (M.B., Ch.B.Liverpool) after examination.

M.Ch.Orth.—May be conferred on graduates in Medicine of Liverpool or other approved university and graduates of a Faculty other than Medicine of Liverpool or other approved university who are Fellows of the Royal College of Surgeons of England, Edinburgh, or Ireland, or of the American College of Surgeons.

Other information concerning the diplomas of this university will be found on page 474.

Fellowships, Scholarships, Exhibitions, and Prizes

The university awards Fellowships annually to students of distinguished merit, as follows:

(1) John Rankin Fellowships in anatomy, two, each of the value of £120, tenable for two years. (2) Ethel Boyce Fellow-

ship in gynaecology, value £100 and tenable for one year. (3) John W. Garrett International Fellowship in bacteriology, value £100 and tenable for one year. (4) Robert Gee Fellowship in human anatomy, value £100 and tenable for one year. (5) Holt Fellowships in physiology and pathology, two in number, value £150 each and tenable for one year. (6) Johnston Colonial Fellowship in biochemistry, value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in surgical pathology, value £150 and tenable for one year. (8) Lady Jones Fellowship in orthopaedic surgery, one, tenable for one year, value £200, offered every two years.

There are, in addition, scholarships, exhibitions, and prizes open to medical students:

Scholarships.—The awards made each year to successful students total over £1,500. They include the following: a University Scholarship of £50, awarded on the results of Part I of the Final M.B. Examinations; a Ridgway Research Scholarship (£94); a T. J. Hughes Research Scholarship (£72); a Scholarship in mechanical dentistry of £20; two Lyon Jones Scholarships, of the annual value of £19 each for two years, awarded one on the results of the First M.B. Examination, the other on the Second M.B.; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Owen T. Williams Prize; the Torr Gold Medal in anatomy; John Rankin Exhibition in practical anatomy, £23; the George Holt Medal in physiology; the Kanthack Medal in pathology; Mitchell Banks Medal in anatomy; the Robert Gee Prize of £5 5s. in children's diseases; Mary Birrell Davies Memorial Scholarship (women), £60 per annum for four years; Robert Gee Entrance Scholarship (men), value of £42 10s. per annum for four years; Dental Operating Prizes (four); Orthodontia Prizes (two); Samuels Memorial Scholarships, three at £27 each; one Thomas H. Bickerton Prize in anatomy; Dr. N. E. Roberts Prize in zymotic diseases; Adami Prize in pathology; Leith Murray Memorial Prize in obstetrics and gynaecology; Rich Prize; J. Hill Abram Prize in pharmacology and general therapeutics; J Hill Abram Prize in medicine; Ash's Prize in dental surgery, value £2 2s.; Gilmour Medal; and other entrance scholarships. In addition, a number of gold and silver medals have recently been instituted in the following subjects: pharmacology, surgery, forensic medicine and toxicology, public health, medicine, orthopaedic surgery, obstetrics and gynaecology, and laryngology and otology.

FEES

Information as to the fees for the courses of instruction should be sought from the Dean of the Medical Faculty.

VICTORIA UNIVERSITY OF MANCHESTER

This university grants the four ordinary degrees in medicine and surgery—M.B. and Ch.B. and M.D. and Ch.M.; degrees and a diploma in dental surgery; a diploma in public health; a diploma in psychological medicine; and a diploma in bacteriology. Candidates for degrees must pass the special matriculation examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof: see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the six years' curriculum, subsequent to the passing of the First M.B. Examination. The matriculation examination comprises (1) Latin, (2) mathematics, (3) English, (4) mechanics, (5) one subject at choice as approved by the Joint Board. It is held in July and September.

Professional Examinations

M.B., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The First M.B. is divided into Part I, chemistry and physics; Part II, biology—(*a*) botany, (*b*) zoology. The parts may be taken separately or together. At the Second M.B. the candidate is examined in anatomy (including histology) and physiology; at the third in pathology, bacteriology, and pharmacology (including materia medica and practical pharmacy). The Final Examination is divided into two parts, which may be taken separately. Part I consists of (*a*) forensic medicine and toxicology, and (*b*) hygiene and preventive medicine. Part II consists of (*a*) medicine, including dermatology, diseases of children, and mental diseases; (*b*) surgery, surgical pathology, and diseases of the eye and of the ear, nose, and throat; (c) obstetrics and gynaecology.

M.D.—A candidate for this degree must be a Bachelor of Medicine of the university of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as a practical and clinical) examination in medicine, a written and practical examination in pathology, and one other subject selected by himself.

Ch.M.—A candidate must have held, since becoming Ch.B., and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery; Branch II, obstetrics and gynaecology; Branch III, ophthalmology; Branch IV, otology, laryngology, and rhinology.

B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in medicine who in their third year of study for the degrees of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. The degree of B.Sc. with Honours in Anatomy or Physiology may be obtained by students in medicine who, after completing the third year of study for the degrees of M.B., Ch.B. devote the following year to the study of the subject of the Honours School. Graduates in science of this university, of not less than one year's standing from the date of their graduation as Bachelors, may proceed to the degree of M.Sc. by the presentation of an approved thesis on some subject coming within the scope of the Faculty of Science.

FEES

The following examination fees are payable: Matriculation, £2; on readmission, £2. Each M.B. examination £8 8s.; on readmission, £3 3s. M.D., including the conferring of the degree, £15 15s. Ch.M., £10 10s. for the examination and £8 8s. for conferment of degree. Application for further information should be addressed to the Dean of the Medical School.

UNIVERSITY OF SHEFFIELD

The degrees of this university (M.B., Ch.B., M.D. and Ch.M., B.D.S., and M.D.S.), and the diploma of licentiate in dental surgery, are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose, and have passed the preliminary examination in chemistry and physics.

Professional Examinations

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 22 years by the day of graduation; that he has pursued the courses of study required by the university regulations during not less than five and a half years subsequent to the date of his matriculation or exemption from matriculation, three of such years at least having been passed in the Faculty of Medicine of the University, one at least being subsequent to the passing of the Second Examination. The following examinations must be passed in due order.

First Examination.—The subjects are chemistry, physics, and biology. Candidates who have passed the Intermediate Examination of the Faculty of Pure Science in any or all of the subjects of the First M.B. Examination will, on payment of the fee for the latter examination, be deemed to have passed it when they have passed in such subjects as they did not take for the Intermediate B.Sc. Examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology; and of having passed or obtained exemption from the preliminary examination in chemistry and physics.

Second Examination.—The subjects are anatomy and physiology (Part I). Candidates must have passed the First Examination, and must have attended (1) courses on anatomy, including lectures and practical anatomy, during five terms; (2) courses on physiology, including lectures and practical physiology, during one year.

Third Examination.—The subjects are pathology and pharmacology, applied anatomy, and physiology (Part II). Candidates must have attended courses of instruction in pathology for five terms, in pharmacology for three terms,

(and one term in pharmacy), in applied anatomy for four terms, and in physiology (Part II) for six terms.

Final Examination.—The subjects are: Part I, forensic medicine, and public health; candidates must have attended courses for one term in each subject. Part II, medicine (including mental diseases, diseases of children, vaccination, special pathology with morbid anatomy and clinical pathology), and therapeutics. Part III, surgery (including the administration of anaesthetics, diseases of the ear, nose, and throat, ophthalmology, and surgical pathology), and obstetrics and gynaecology (including ante-natal and post-natal practice and infant hygiene. Candidates for Parts II and III must have completed a minimum of five and a half years of study.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least three years previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.M.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least three years previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than twelve months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES

The Welsh National School of Medicine

The university grants degrees in Medicine and Surgery—Bachelor in Medicine and Bachelor in Surgery (M.B., B.Ch.), Doctor in Medicine (M.D.), and Master in Surgery (M.Ch.)—and Diplomas in Public Health (D.P.H.), and Tuberculous Diseases (T.D.D.).

M.B. and B.Ch. Degrees—Candidates are required to pursue a course of study of not less than six academic years subsequent to their matriculation in the university. They must hold an arts or science degree of the University of Wales, or of some other university approved for the purpose, but certain of the courses pursued for a B.Sc. or a B.A. degree may be counted as required for the medical degrees. The courses for the M.B., B.Ch. are divided into two sections. The first includes Physics, Chemistry, Botany, and Zoology (Preliminary Subjects); Organic Chemistry (Subsidiary Subject); Human Anatomy and Physiology (Ancillary Subjects). Study of the preliminary subjects and of Organic Chemistry must extend over at least one academic year; study of Physiology and Human Anatomy must extend over at least two academic years; the first section of the course must occupy not less than three years. The second section includes courses in Materia Medica and Pharmacology, Pathology and Bacteriology, Hygiene and Forensic Medicine, Medicine, Surgery, and Obstetrics and Gynaecology. These courses cannot be commenced until the examinations of the first section have been completed. Examinations in all subjects of the second section are held twice each year.

M.D. Degree.—Every candidate for the degree of *Doctor in Medicina* shall satisfy the examiners in an examination in clinical medicine and shall submit a thesis to the judgement of the university. A candidate may present himself for the examination in clinical medicine during or subsequently to the second year after qualification for the degrees of *Baccalaureus in Medicina* and *Baccalaureus in Chirurgia*, and may submit his thesis during or subsequently to the third year after qualification for those degrees. The thesis shall embody the results of the candidate's personal observation or original research in some branch of medical knowledge or of some science directly relative to medicine, excepting a subject that is exclusively surgical. The candidate shall indicate in what respects his thesis appears to him to advance medical knowledge or practice. A candidate shall be required to submit himself to an oral or other examination on the subject-matter of the thesis; provided always that in exceptional circumstances it shall be within the discretion of the university to exempt a candidate from such an examination.

M.Ch. Degree.—Every candidate for the degree of *Magister in Chirurgia* shall satisfy the examiners in an examination in Surgery and shall submit a thesis to the judgement of the university. A candidate may present himself for the examination in Surgery during or subsequently to the second year after qualification for the degrees of *Baccalaureus in Medicina* and *Baccalaureus in Chirurgia*, and may submit his thesis during or subsequently to the third year after qualification for those degrees. The examination in Surgery shall consist of two parts: Part I—(i) Surgical Anatomy, (ii) Bacteriology and Surgical Pathology; Part II—(i) Surgery, (ii) Clinical Surgery, (iii) Operative Surgery. No candidate shall be deemed to have passed in Part II unless he has satisfied the examiners in Part I of the examination. The thesis shall embody the results of the candidate's personal observation or original research in some branch of surgical knowledge or of some science directly relative to surgery. The candidate shall indicate in what respects his thesis appears to him to advance surgical knowledge or practice. A candidate shall be required to submit himself to an oral or other examination on the subject-matter of his thesis; provided always that in exceptional circumstances it shall be within the discretion of the university to exempt a candidate from such examination.

Clinical Institutions.—Clinical teaching is carried out in the Cardiff Royal Infirmary (489 beds); the Llandough Hospital (City of Cardiff) (345 beds); the City Lodge Hospital (City of Cardiff) (604 beds); the Cardiff City Mental Hospital (790 beds); the Cardiff City Isolation Hospital (230 beds); the Prince of Wales' Hospital (Orthopaedic) (132 beds); the Cefn Mably, Glan Ely, and Sully Hospitals (Tuberculosis) (608 beds); the Lord Pontypridd Hospital (acute Rheumatism of Children) (25 beds). These institutions are modern and well equipped, and provide facilities for both in-patient and out-patient clinical instruction. The Cardiff Royal Infirmary is the main teaching hospital. It serves a district having a population of more than half a million, and during the year 1936 6,268 patients were admitted to the wards, and 39,875 patients treated in the out-patient departments.

Scholarships, Free Studentships, Prizes, and Medals.—Entrance Scholarships, County Free Studentships, and Scholarships are available. Particulars of these are contained in a special prospectus, which can be obtained on application. An Isaac Roberts Scholarship in Science, of the value of £50 per annum, tenable for three years, is awarded triennially on the results of the Entrance Scholarship Examination of the Cardiff College. The Samuel Brothers' Scholarship, value £12 to £15, is awarded annually on the results of the work of the first year medical course at Cardiff College. The Dr. Price Prize, value £50, is awarded annually on the results of the work of the first year of the medical course at the Cardiff College. The Dr. Howell Rees Scholarship, value £17 10s., is awarded triennially, and is held in The Welsh National School of Medicine; it is awarded on the results of the examinations in anatomy and physiology. Numerous other prizes are awarded for proficiency in different subjects.

Research Scholarships.—A Catherine Buckton Scholarship of £60 for one year is offered periodically by the council of Aberdare Hall (one of the halls of residence for women students) to a woman who shall undertake to do postgraduate work. The Mrs. John Nixon Research Scholarship of £150 per annum is available for the promotion of research in Medicine and Medical Pathology. The Lord Merthyr Research Scholarship, value £200 per annum, is available for the promotion of research in cancer. A Cecil Prosser Research Scholarship, value £250 per annum, is available for the promotion of research in tuberculosis. The Ewen Maclean Research Scholarship, value £150 per annum, is available for the promotion of research into the factors which constitute and the conditions which vary resistance to disease, especially as regards midwifery. Inquiries should be addressed to the Secretary, Welsh National School of Medicine, 10, The Parade, Cardiff.

English Medical Corporations

There are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges, and the third licensing body here follow.

THE CONJOINT BOARD

This body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.R.C.P.Lond., M.R.C.S.Eng. It performs the same task in connexion with diplomas in public health, tropical medicine and hygiene, ophthalmic medicine and surgery, psychological medicine, laryngology and otology, medical radiology, anaesthetics, and child health, jointly issued by the two Colleges. Under the present regulations every candidate for the L.R.C.P. and M.R.C.S. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics; (2) comply with the regulations, which may be had from the Secretary, Examination Hall, Queen Square, London, W.C.1; and (3) pass the two professional examinations of which particulars appear below.

Regulations for the Conjoint Diplomas

The following is an outline of the present regulations for the L.R.C.P.Lond. and M.R.C.S.Eng. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

PRE-MEDICAL EXAMINATION

Students are required to pass a pre-medical examination in chemistry, physics, and elementary biology, conducted by the Conjoint Examining Board, before commencing the five years' curriculum of professional study, or some other examination recognized by the Board—namely, the examination in chemistry, physics, and biology for the degree in Medicine of any university recognized by the Board, the higher school certificates of Oxford and Cambridge Universities and the Oxford and Cambridge Schools Examination Board, the higher certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, or the Central Welsh Board higher certificate.

A candidate must enter for chemistry and physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required preliminary examination in general education.

The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months. Not more than two terms of professional study is recognized before the examination in elementary biology is passed.

PROFESSIONAL EXAMINATIONS

There are two professional examinations, called the First and Final Examinations. The courses of study for the First Examination may be commenced before the pre-medical examination in biology or some equivalent examination has been passed provided three terms of study of anatomy and physiology are completed after passing such examination.

First Professional Examination.—The subjects of this are: Section I, (*a*) Anatomy, including histology and embryology; (*b*) Physiology, including biochemistry. Section II, Pharmacology and materia medica. A candidate must have attended at a recognized Medical School courses of instruction in anatomy, including embryology, during five terms, in the course of which he must have dissected the whole body; courses of instruction in physiology, including biochemistry and biophysics, during five terms; courses of instruction in pharmacology and materia medica. A candidate may present himself for the two sections together or separately, but he must take parts (*a*) and (*b*) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination, provided that the courses for admission to Section I have been completed. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of this are: Section I, Pathology (including morbid anatomy, morbid histology, and clinical pathology) and Bacteriology. Section II, Part I, Medicine, including medical anatomy, forensic medicine, and public health; Part II, Surgery, including surgical anatomy and the use of surgical appliances; Part III, Midwifery and gynaecology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately, or may take the whole examination together. He will be required to produce the certificates prescribed by the regulations before being admitted to the respective parts of the examination. No exemption is granted from any subject in the Final Examination.

FEES

The fee for the *Pre-Medical Examination* is four guineas, for re-examination in Chemistry two guineas, for re-examination in Physics one guinea, and for Biology one guinea. The fee for the *First Professional Examination* is ten guineas, for re-examination after rejection in Section I six guineas, for re-examination after rejection in either part of Section I three guineas, for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the *Final Professional Examination* is four guineas; for admission to Section II, Part I, ten guineas; Part II, ten guineas; Part III, six guineas; and the re-examination fees are respectively three guineas, six guineas, six guineas, and five guineas.

Royal College of Physicians of London

This College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership (examinations for which are held in January, April, July, and October) is only granted to those who have obtained the Licence or to those who are graduates of a recognized university; in any case they must be persons over 23 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce; they are also examined in French and German. The languages are not compulsory, but credit is given to those who show a knowledge of them. The fee for the Membership is £42, or in the case of a Licentiate £21. There is a fee of £10 10s., payable before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

Royal College of Surgeons of England

This College conducts examinations for the Membership and for the Fellowship. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the Primary in anatomy and physiology, held in the months of June and December, which may be passed after the third winter session; the Final held in the months of May and November, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose. All candidates are required to have held for six consecutive months a responsible post in charge of general surgical patients

in the wards of a general hospital recognized by the Council.

Fees.—At First Examination, £8 8s. (for re-examination, £5 5s.). At Second Examination, £15 15s: Admission fee £10 10s. for members, £31 10s. for non-members.

Society of Apothecaries of London

This Society confers a registrable diploma in medicine, surgery, and midwifery (Licentiate in Medicine and Surgery of the Society of Apothecaries, L.M.S.S.A.), on those successful at the following examinations:

Pre-medical Examination.—Chemistry and physics, and elementary biology.

Primary Examination.—This includes anatomy, physiology and histology, written, oral, and practical, and materia medica and pharmacy, written and oral. Candidates referred in anatomy or physiology will be required to produce evidence of further study before being admitted to re-examination. Candidates will be excused any or all the subjects of the Pre-Medical and Primary Examination on producing evidence that they have passed the equivalent examinations before an examining body recognized by the Society.

Final Examination.—This is divided into three sections, which may be taken at separate examinations—namely, A, B + D, and C. A, Principles and practice of surgery, including surgical pathology, surgical anatomy, operative manipulation, instruments and appliances; B, Principles and practice of medicine, including therapeutics, pharmacology, and prescriptions), general and medical pathology, bacteriology, and morbid histology; C, Midwifery, gynaecology, diseases of newborn children, obstetric instruments and appliances; D, Forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. A, B, and C are written, oral, and clinical. D is written and oral. There is no exemption from any subject of the Final Examination. Candidates referred in A, B, or C will be required to produce evidence of further study before re-examination.

The fee for the Pre-medical Examination is £5 5s.; for the Primary and Final, £21, payable in two instalments. The regulations and synopses relating to the several examinations, and other information, may be obtained from the Registrar, The Society of Apothecaries, Water Lane, Queen Victoria Street, E.C.4. (telephone Central 1189).

MASTERY OF MIDWIFERY

The Society in 1928 instituted a Mastery in Midwifery, and issues a diploma under this title denoting the possession of specialized knowledge of ante-natal care, midwifery, and infant welfare, and the public health aspects of these subjects. The examinations take place in May and November, and candidates are required to submit certificates, etc., twenty-one days before date of examination. A severe test has been imposed so as to ensure a high standard of professional knowledge, but the diploma is not registrable under the Medical Acts. Admission is open to all who have been for not less than three years in possession of a registrable medical qualification, and who have had certain prescribed experience at recognized institutions concerned with obstetrics, ante-natal work, and infant welfare work. Medical officers employed by a public health authority, and having special duties connected with maternity and child welfare, are admitted to the examination on production of evidence to that effect. The entrance fee for the examination is £10 10s., and a further fee of £10 10s. is payable by successful candidates before admission to the Mastery. Copies of the regulations may be obtained from the Registrar at the address given in the preceding paragraph.

British College of Obstetricians and Gynaecologists

One of the principal objects of the College is to encourage the study and practice of obstetrics and gynaecology, subjects which should be inseparably interwoven. The College consists of Fellows and Members.

Candidates for the Membership must have been entered on the British *Medical Register* for at least three years or be eligible for entry thereon. Before being accepted for the examination they must produce evidence, satisfactory to the examination committee, of having held resident hospital appointments in general medicine or surgery and in obstetrics and gynaecology for the period laid down in the regulations (at present six months each). The examination consists of the presentation of case records and commentaries, two written papers, and an oral and clinical examination. The Fellowship is granted to those Members who are judged to have advanced the science and art of obstetrics and gynaecology.

The Fellowship and Membership include practically every teacher of obstetrics and gynaecology in Great Britain and the British Dominions. Fellowship or Membership is now a necessary qualification for election to the staff of many obstetric and gynaecological hospitals, and it is anticipated that in time it will be essential for election to the staff of all such hospitals; consequently all intending to specialize in obstetrics and gynaecology should endeavour to obtain the Membership as soon as possible.

For those practitioners who have had special post-graduate experience in obstetrics, but whose experience and work do not allow of their admission to the Membership, the College grants a diploma (D.C.O.G.). Candidates for it must be entered on the British *Medical Register*. They must produce evidence of resident post-graduate experience in obstetrics as well as in general medicine or surgery. Evidence of having regularly attended at ante-natal, post-natal, and infant welfare clinics and a satisfactory course in gynaecology is also required.

The D.C.O.G. is intended to indicate that the holder is a competent obstetrician and one who may be regarded as sufficiently capable to act in the capacity of consultant to local authorities in midwifery practice. The examination does not, however, include gynaecology except in so far as it is directly associated with child-bearing, and this diploma is not meant for those who aspire to hospital appointments with charge of gynaecological beds.

The regulations governing the Membership and diploma may be obtained from the honorary secretary, British College of Obstetricians and Gynaecologists, 58, Queen Anne Street, London, W.1.

SCOTLAND

THE UNIVERSITIES

There are in Scotland four universities, each possessing a Faculty of Medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of St. Andrews, Glasgow, Aberdeen, and Edinburgh. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also diplomas in psychiatry and medical radiology. As for public health, registrable degrees and diplomas in this subject are granted by the University of Glasgow, while diplomas in public health may be obtained from the Universities of Edinburgh, St. Andrews, and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts or Science. Prospective medical students are also required

to pass a pre-registration examination in chemistry and physics. This is not enforced at Aberdeen or at St. Andrews.

Professional Education

The regulations comply in all respects with the requirements and recommendations of the General Medical Council. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study not less than three (or in certain circumstances two) must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the beginning of July.

Professional Examinations

The distinctive feature of the Scottish curriculum is that though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology* and chemistry.† At the end of the first summer session he can finish with botany* and physics,† and with anatomy and physiology at the end of the second. Pathology and materia medica he may pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with much distinction" or "with distinction"—"with merit" in St. Andrews—and a record is kept of the merit displayed, so that when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with honours. (In Glasgow and in Edinburgh a candidate may pass "with distinction," but there is no higher grade of "much distinction.") A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry (inorganic and organic); the second with anatomy and physiology; the third with materia medica, therapeutics, pathology, and bacteriology; the fourth with forensic medicine, public health, medicine, surgery, midwifery, and gynaecology. At Edinburgh the first two examinations are held three times a year, except in chemistry and zoology, in which subjects examinations are held only twice a year. At St. Andrews all four examinations are held twice a year, and at Glasgow the first two are held twice a year and the third three times. At Aberdeen, degree examinations in all subjects are held twice a year.

Exemption from the first professional examination may be obtained by candidates who have passed an arts, science, or medical degree examination in its subjects at any recognized university.‡

The Higher Degrees

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Service, or have been at least two years in general practice, and must be at least 24 years of age. A thesis on any subject not exclusively surgical must be submitted, and the candidate is also examined in clinical medicine and, if desired (or, in the case of Glasgow, St. Andrews, and Aberdeen), in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. An examination in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery, is included.

FEES

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £265, the separate examination fees included in this calculation being as follows:

	£ s. d.
First Professional	9 9 0
Second Professional	7 7 0
Third Professional	6 6 0
Final	11 11 0

(At Glasgow the fees are respectively nine, nine, eight, and seven guineas; at St. Andrews nine, six, nine, nine respectively.)

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £21, and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d. (by post 7½d.), which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Information about Glasgow should be sought from the Registrar, the University, Glasgow. With regard to Aberdeen, application should be made to the Secretary of the University of Aberdeen. In respect of St. Andrews, information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

The Carnegie Trust

The following is a summary of the regulations made by the Carnegie Trust for the Universities of Scotland for assistance in the payment of class fees in the universities and extra-mural colleges of Scotland.

Applicants must be over 16 years of age; they must be of Scottish birth or extraction, or have attended for two years, after the age of 14, at a school or institution under inspection of the Scottish Education Department. Applicants so qualified who have been pupils of schools under the Scottish Education Department will be eligible for assistance in the payment of class fees if they have obtained the leaving certificate of the Department with a minimum of three higher grade passes, provided that it bears evidence of such preliminary education as is required by the universities for their graduating curricula, or that it has been supplemented by such passes either in the Scottish Universities Preliminary or other examination as will satisfy the above requirement of the universities before they begin their graduating curricula. Where applicants have not been pupils of schools under the Scottish Education Department, or where other good ground for not having obtained the leaving certificate can be shown, the Executive Committee has power to accept instead what it deems equivalent evidence of attainments provided that applicants will not be considered eligible who have not obtained three higher grade passes or who require to pass any further preliminary examination before they begin their graduating curricula. No applicant in medicine is eligible for assistance until pre-registration subjects have been passed at any centre where pre-registration examinations are required.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adviser of Studies, and all applicants must have passed the graduation examinations belonging to the

* At St. Andrews University botany and zoology may be taken at the end of the first winter term, physics and chemistry at the end of the first year.

† In the case of Glasgow these subjects—chemistry and physics—are transposed.

‡ This does not apply to the University of Aberdeen, where the course in physics includes special instruction on the medical aspects of the subject. Accordingly every student, irrespective of whether he holds an arts or science pass in physics, must take medical physics.

previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their attendance and work, any distinctions gained, and any graduation examination passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £20 for four years, in all £80. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are: Arts and Medicine—two Arts grants of £9 and four Medicine grants of £20, in all £98; Science and Medicine—two Science grants of £18 and four Medicine grants of £20, in all £116.

Applicants, in writing for application forms (Carnegie Trust, Merchants' Hall, 22, Hanover Street, Edinburgh), must name the university and faculty in which they intend to study, and state whether they have previously obtained the benefits of the Trust. Fully completed application forms must be lodged by new beneficiaries not later than October 20 for the winter session, and by former beneficiaries not later than October 25. Applications for the summer session must be lodged not later than May 10. Payments are made by means of fee coupons, and fees already paid are not refunded.

THE SCOTTISH CORPORATIONS

There are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board, which the three corporations have combined to form. Details concerning this Board and its component Colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

The Conjoint Board in Scotland

This body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P.Ed., L.R.C.S.Ed., and L.R.F.P.S.Glas. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

PROFESSIONAL CURRICULUM FOR CANDIDATES REGISTERED AS MEDICAL STUDENTS AFTER OCTOBER 1, 1930

Subsequent to registration as a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held twice in Edinburgh and twice in Glasgow during the next period; it is open to candidates to present themselves for examination at either place. The First Examination deals with general biology (systematic and practical), and physics and chemistry (systematic and practical); the second with anatomy, embryology, physiology, biochemistry, and biophysics; the third with pathology (including bacteriology and morbid anatomy) and pharmacology (theoretical and practical); and the final with (1) medicine, including therapeutics, applied anatomy and physiology, and clinical pathology, with practical medicine; (2) surgery, including applied anatomy and physiology, clinical pathology, and practical surgery; (3) midwifery and diseases of women, clinical obstetrics and gynaecology, with practical midwifery; and (4) medical jurisprudence and public health. All candidates for the Final Examination must complete portions (1), (2), and (3), which must be taken together, within a period of nineteen months.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the Final Examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the Third Examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own, but all candidates for the Conjoint Licence must sit for the Final Examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

FEES

It is estimated that the total cost of lectures and fees for the Conjoint Licence is about £170. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final, £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects of the First, Second, or Third Examination the fees are smaller.

Information concerning this Board should be sought either from Mr. David Thomson, Solicitor, 18, Nicolson Street, Edinburgh, or from Mr. David Willox, Faculty Hall, 242, St. Vincent Street, Glasgow.

Royal College of Physicians of Edinburgh

This College has three grades—Licentiateship, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiateship have already been generally indicated. If desirous of receiving it apart from those of the other two corporations, they must be duly registered medical practitioners. Candidates will be required to pass an examination corresponding to the medical part of the final examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday and Thursday, except in September and October.

Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, also on one or more departments of medicine specially professed, and approved by the Council, in which a high standard of proficiency will be expected. The fee to be paid by a candidate for the Membership is £36 15s. The examination is held quarterly, on the second Tuesday and following days of the months of January, April, July, and October, and application for admission to it must be made a month previous to the date at which it is proposed to appear.

For the Fellowship the candidate must have been a Member of the College for at least three years, and if accepted, pay fees, including £25 stamp duty, amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

Royal College of Surgeons of Edinburgh

This College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

Licence

As an original qualification the Licence is only granted after fulfilment of the regulations of the Scottish Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable or equivalent qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates.

Fellowship

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of their profession subsequent to qualification for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (*a*) the principles and practice of surgery, including surgical anatomy, (*b*) clinical surgery, and (*c*) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology and rhinology, gynaecology, obstetric surgery, anatomy, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice. After having passed the examination he must lodge with the Clerk to the College a petition asking that his name be placed before the College for election as a Fellow. This petition must be signed by two Fellows, as proposer and seconder, who should be sufficiently acquainted with the candidate to vouch that he is in every way a suitable candidate for the Fellowship. Examinations are held four times a year—January, March, July, and September. It is desirable that either the proposer or the seconder should be resident in Edinburgh. Candidates are not allowed to appear more than three times at the examinations unless by express permission of the President's Council.

The admission fee is £20, and after passing the examination the candidate shall pay the sum of £30 to the College funds. In the case of Licentiates of the College £10 thereof shall be remitted in consideration of the fees they have already paid. For further information application should be made to the Clerk of the College, Mr. David Thomson, Solicitor, Surgeons' Hall, 18, Nicolson Street, Edinburgh, from whom a copy of the *Laws Relating to the Fellowship by Examination* may be obtained.

Royal Faculty of Physicians and Surgeons of Glasgow

The Royal Faculty of Physicians and Surgeons grants, after examination, a Fellowship which is registrable by the General Medical Council as an additional qualification. For the Fellowship *qua* physician or the Fellowship *qua* surgeon, the candidate must pass in medicine or surgery as the primary subject and an additional subject cognate with medicine or surgery respectively must also be taken at the same examination. Candidates are required to be approved by the Council before admission to the examination. Successful candidates are later balloted for election by the Faculty and, if elected, are duly admitted *qua* physician or *qua* surgeon. The fee for admission to the Fellowship is £50, or for Licentiates of the Faculty, £40. Examinations are held quarterly.

The Faculty grants, after examination, a single licence. Candidates for admission to the examination for the single licence must produce satisfactory evidence that they are in possession of a medical qualification registrable in the British *Medical Register*.

The regulations respecting the Fellowship together with the dates of the Examinations may be obtained on application to the Secretary, Royal Faculty of Physicians and Surgeons, 242, St. Vincent Street, Glasgow, C.2.

IRELAND

MEDICAL REGISTRATION IN THE IRISH FREE STATE

The Medical Practitioners Act, 1927 (Irish Free State), provides for the establishment of a Medical Registration Council for the Irish Free State. The main functions of the Council are (1) to keep a register of medical practitioners who may desire to practise permanently or temporarily in the Irish Free State, and (2) to exercise disciplinary power with regard to all medical practitioners who are on the *Register* and engaged in practice in the Irish Free State. The first schedule of the Act contains the agreement between Great Britain, the Irish Free State, and Northern Ireland. This agreement provides for the nomination of a member of the General Medical Council, formerly made for Ireland by His Majesty on the advice of the Privy Council, to be made henceforth by His Majesty in Council on the recommendation of the Governor of Northern Ireland. The nominations of members of the General Medical Council by universities and medical corporations in Ireland and the election of a member of the General Medical Council by registered medical practitioners in Ireland will be in all respects the same as heretofore. The constitution of the General Medical Council and of the several Branch Councils as formerly existing under the Medical Acts, and the powers of holding qualifying examinations and granting diplomas for the purpose of registration in the general *Register* formerly vested in certain universities and medical corporations in Ireland, are not affected by the establishment of the Irish Free State or of Northern Ireland, and for the purpose of the preparation and keeping of the general *Register* the General Medical Council and the Branch Council for Ireland have the same powers and jurisdictions under the Medical Acts as they exercised formerly. The agreement provides also that any person who is or shall be registered in the general *Register* shall be entitled on the payment of a prescribed fee to be registered in the *Irish Free State Register*, but this fee is not payable by any person who, on the date of the establishment of the *Irish Free State Medical Register*, is registered on the general *Register*. Then follow provisions with regard to the erasure from the *Register* of the name of a person on account of misconduct.

The *Irish Free State Medical Register* was established on May 26, 1928, this being the date appointed by the Medical Registration Council. The *Register* on establishment contained the name of every medical practitioner who was registered in the general *Medical Register* immediately before May 26, 1928, and who either was then resident in the Free State, according to his address as stated in the general *Register*, or was living outside the Free State and applied to the Council within one month before May 26, 1928, to be registered. No fee for registration was charged in such cases.

For registration in the *Irish Free State Medical Register* subsequent to its establishment a fee is required, together with a prescribed form of application. A person is eligible for registration if he is at the time of application registered in the general *Medical Register*, or if he possesses the requisite qualifying diploma granted by the colleges or bodies in the Free State as set out in the Act. Candidates for medical appointments made under the Appointments Commission must be registered in the *Irish Free State*

Medical Register. Application for further information may be made to the Registrar, Medical Registration Council, Room 35, Upper Fitzwilliam Street, Dublin.

THE IRISH UNIVERSITIES

There are three universities in Ireland, each with a medical faculty. These are, in the Irish Free State, the University of Dublin (usually known as Trinity College, Dublin), and the National University of Ireland; and, in Northern Ireland, the Queen's University of Belfast.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and a postgraduate diploma in public health. It also grants postgraduate diplomas in gynaecology and obstetrics, for which nine months' study is required, and in psychological medicine, for which twelve months' study is required. The degrees are granted to those who, having passed the professional examination, have also graduated in arts.

Professional Examinations

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

Preliminary Scientific.—This covers (*a*) chemistry, (*b*) physics, (*c*) botany and zoology. The three divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (*a*) anatomy, physiology, and histology; (*b*) applied anatomy and applied (clinical) physiology. The two parts may be taken separately or together.

Final Examination.—Part I: Pathology and bacteriology, materia medica and therapeutics. Part II: (*a*) Midwifery and gynaecology; (*b*) medicine, mental diseases, medical jurisprudence and hygiene; (*c*) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the Final Examination cannot be completed before the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and also examine him viva voce in general medicine.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing and must produce satisfactory evidence of having been engaged in practice for two years.

M.A.O.—The candidate must be a B.A.O. of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in the study or practice of obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY, BELFAST

The degrees granted by the Medical Faculty of this University are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health and a diploma in psychological medicine. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B.D.S. and M.D.S.) are conferred by the university, and also a diploma in dental surgery (L.D.S.).

Professional Examinations

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology (both theoretical and practical), and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) pathology, bacteriology, and practical pathology and practical bacteriology, (2) materia medica, pharmacology and therapeutics, (3) medical jurisprudence, and (4) hygiene. Candidates who have passed the Second Examination may present themselves for Part I of the Third (Nos. 1 and 2) at the close of the third year, and for Part II (Nos. 3 and 4) at the end of the winter session of the fourth year.

The Final Examination includes: (1) medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student must pass in all subjects at once at the end of his fifth year. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

The Higher Degrees

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (*a*) after a formal examination, or (*b*) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (*a*) human anatomy, including embryology; (*b*) physiology, (*c*) pathology, (*d*) pharmacology and therapeutics, (*e*) sanitary science and public health, (*f*) forensic medicine and toxicology, (*g*) mental diseases, (*h*) infant hygiene and diseases of children, (*i*) midwifery and infant hygiene. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND

The National University of Ireland carries on most of its medical educational work through three constituent colleges—University College, Dublin; University College, Cork; and University College, Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation in the Medical Faculty. The candidates at each constituent college are examined by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the General Board of Studies of the university. In addition to the ordinary degrees in Medicine and Surgery the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as Diplomas in Public Health and in Psychological Medicine.

Application for other information may be made to the Registrar, National University of Ireland, 49, Merrion Square, Dublin, C.17.

THE IRISH CORPORATIONS

There are, in the Irish Free State, three licensing bodies other than the Medical Faculties of the universities; and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall. In Dublin, as in London and in Edinburgh, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

THE CONJOINT BOARD IN IRELAND

This body requires of candidates either the passage of its own preliminary examination in the subject of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the pre-registration examinations in chemistry and physics and biology.

Professional Examinations

There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The First Examination deals with Part I—(*a*) biology, (*b*) applied chemistry and physics. Part II—anatomy, including embryology; physiology, including physiological chemistry and histology. The Second Examination deals with (*a*) pathology, including morbid anatomy, clinical pathology, and bacteriology; (*b*) materia medica, pharmacy, and therapeutics; (*c*) forensic medicine, hygiene, and public health; (*d*) ophthalmology and aural surgery; and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the pre-registration examinations, and five years at least since the beginning of the curriculum. The divisions are: (*a*) medicine, including fevers, mental diseases, and diseases of children; (*b*) surgery, including operative surgery; (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination.

Fees.—Preliminary Examination, £2 2s. Re-examination, £2 2s. Pre-Registration Examination, £3 3s. Re-examination in Chemistry, £2 2s.; in Physics, £1 1s. First Professional Examination—Part I, £17 17s.; Part II, £10 10s.; Second, £9 9s.; Final, £6 6s. Re-examination fee is £2 2s. for each division.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green, Dublin.

Royal College of Physicians of Ireland

Those whose names already appear on the *Medical Register* of the General Medical Council or of Saorstat Eireann can obtain the separate Licence in Medicine of this College and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to graduates in medicine of recognized universities whose names are on the *Medical Register* of the United Kingdom or the Irish Free State, and Licentiates in medicine of the Royal Colleges of Physicians. The examination deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College.

Fees.—For the Licence in Medicine, 15 guineas; Special Examination, £21. For the Licence in Midwifery, 8 guineas; Special Examination, 16 guineas. For the Membership, 20 guineas to a Licentiate of the College, 35 guineas to others; a special examination costs 10 guineas extra. The Fellowship, £35, in addition to stamp duty, £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

Royal College of Surgeons in Ireland

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the Royal College of Physicians, but it is given separately to holders of a registrable qualification in medicine provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce; while the Final Examination includes the performance of operations. All subjects of either examination must be passed at one time, and in neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*; if, however, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

Apothecaries' Hall of Ireland

A diploma is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Women candidates are eligible.

Fees.—First and Second Professional Examinations, £21; Final Examination, £21. Subjects of examination: First Professional, Anatomy and Physiology. Second Professional, Materia Medica and Pharmacy; Medical Jurisprudence and Hygiene; Pathology. Final Examination: Medicine, Surgery, and Midwifery. Candidates must enter for and pass at the one time in Anatomy and Physiology. They are at liberty to enter for the subjects of the Final Examination at separate times, but the Final Examination cannot be completed until a period of three years has elapsed from the date of passing the First Professional Examination.

Applications should be sent to the Registrar (Dr. T. G. McGrath), or to the Secretary (Mr. Jos. F. Kennedy), from either of whom all information can be had. The address is Apothecaries' Hall of Ireland, 95, Merrion Square, Dublin.

Medical Schools and Colleges

LONDON

Information as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

Charing Cross Hospital

Situated in the centre of London, Charing Cross Hospital Medical School is the most easily accessible of all the London schools. Instruction is given in all the subjects for the final examinations of the universities of London, Oxford, and Cambridge, the Conjoint Board, and other licensing bodies. A particular feature of the school is that, by limiting the number of admissions to 30 students a year, they are in constant and intimate contact with the staff throughout the clinical period. The "firms" have no more than five clerks or dressers, and each student has the care of not less than six beds. The policy of the School is to concentrate on undergraduate teaching. In addition to the clinical appointments held by every student, courses of systematic lectures, demonstrations, and tutorial classes are held in all subjects of the curriculum. In the School there are departments devoted to bacteriology, clinical pathology, biochemistry, materia medica, public health, operative surgery, as well as laboratories for research. By reason of the abundance and variety of the material available for investigation, the Institute of Pathology, with its whole-time staff of scientific workers and its completely equipped laboratories, offers peculiar advantages to students in this branch of medicine. The Library has ample accommodation, and contains over 4,000 volumes, including modern textbooks and contemporary reviews. The Pathological Museum is organized in two sections: one devoted to specimens illustrating general conditions; the other consisting of the Lockyer Collection, one of the finest collections of gynaecological and obstetrical specimens in the country.

The hospital contains 300 beds. Of this number, 93 are allocated to medical cases, 92 to surgical, and 41 to obstetric and gynaecological. The remainder are distributed between the special departments. There are special departments for diseases of ear, nose, and throat, the eye, the skin, for children, for mental disorders and psychological medicine, for orthopaedic surgery and massage, for *x*-ray, electrical, and light treatment, for dental surgery, and for tuberculous and diabetic cases. In addition to the number of beds set apart for diseases peculiar to women and for midwifery cases, the hospital serves an extensive and thickly populated district in gynaecological and obstetric work. In-patients numbered 5,156 last year and the out-patient department dealt with 32,614 new cases. Out-patient attendances totalled 165,732.

The Students' Club provides for the athletic, recreational, and social life of the students by means of an 8-acre sports ground, with facilities for football, cricket, hockey, tennis, and badminton, by common rooms, restaurant, etc., and by sections of the club designed for a particular purpose, such as the debating society and the dramatic society. Plans have been passed for the erection of a new permanent brick-built pavilion providing complete accommodation for the club at the sports ground at Colindale.

Appointments.—The number of resident appointments as compared with the number of students in the School is exceptionally large, and students of reasonable ability and industry can usually be certain of obtaining one or more. The resident appointments, to which election is made every six months, number 13 (26 every year). During the time an appointment is held the officer receives a salary, and he is provided with free board and accommodation in the Residency of the hospital. In addition to the foregoing, two non-resident officers and a number of clinical assistants are appointed annually. Higher appointments.—Annual election is made to the posts of resident medical officer (£400), resident casualty officer (£200), medical registrars (two, £150 each), surgical registrars (two, £150 each), obstetric registrar (£100), and registrar to the ear, nose, and throat departments (£100). The holders of these posts are eligible for election for a second year. Every student during the course of his clinical studies serves the offices of medical clerk, surgical dresser, and clerk and dresser to all the special departments.

Scholarships.—The following are offered annually: (*a*) For students beginning medical studies, two scholarships, each of the value of £50. (*b*) For students beginning clinical studies, two University Scholarships, each of the value of £120, in pathology; one University Scholarship, value £120; and one Open Scholarship, value £75, in anatomy and physiology. An "Epsom College" Scholarship (£100) is awarded periodically on the nomination of the Head Master, and a "Cranleigh" Scholarship on similar conditions. In addition there are a number of exhibitions.

Prizes.—(1) The Llewellyn Prize (25), and the Llewellyn Certificate of Merit (with £10) for highest distinction throughout final course of studies. (2) Williams Travers Prize, £15, midwifery and gynaecology. (3) Pereira Prize, £5 5s., clinical commentary. (4) T. H. Green Prize, £5 5s., clinical commentary. (5) Clinical Surgery Prize, £3 3s. (6) Clinical Medicine Prize, £3 3s. (7) John H. Morgan Prize, £10. (8) Dr. H. W. C. Vines Prize in Pathology, £5. (9) Steadman Prize in Pathology, £2 2s. (10) Dr. Russell Reynolds Prize in Radiology, £5. (11) The Governors' Clinical Gold Medal. (12) Class Prizes of £2 2s. each in Hygiene and Public Health; Ophthalmology, Oto-laryngology; Psychological Medicine; Midwifery; Practical Midwifery; Gynaecology; and Pharmacology and Therapeutics.

Fees.—The fees are as follows: Entrance fee, £10 10s.; annual fee, 38 guineas. Annual subscription to Students' Club, £4 4s.

Male students only are admitted.

Further information may be obtained on application to Eric A. Crook, M.Ch., F.R.C.S., Dean of the Medical School, Charing Cross Hospital, London, W.C.2.

Guy's Hospital

The hospital contains 625 beds in constant occupation. Twenty-five beds are set apart for diseases of the eye, and there are special wards for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the ear, nose, and throat department, the departments of orthopaedics, neurology, and dermatology, the department for the treatment of diseases of the genito-urinary system, and the children's department; there are also some special beds for the treatment of syphilis.

The residential college fronts the east gate of the hospital, providing accommodation for resident students. This contains a dining hall, smoking room, reading room, a library of general literature, and a gymnasium for the use of the residents and members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in fifteen minutes. The Gordon Museum of Pathology, the Wills Library, the departments of chemistry, physics, biology, pathology, and pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research, and provide the full curriculum for all medical degrees and diplomas. The departments of anatomy, physics, and biology have been reconstructed and equipped on the most modern lines, and provide ample accommodation for teaching and research. At the present time a large extension of the medical school is in process of being built, and it is hoped that it will be opened in the summer term of 1938. It will provide accommodation for pathology, including

bacteriology and clinical chemistry. Ample accommodation will be available both for teaching and for research. In addition the new building, which will communicate with the existing building, will house both physics and pharmacology, setting free accommodation in the existing building, which will be devoted to enlarging the Departments of Anatomy, Physiology, and Biology. Special classes are held for the first and second examinations for medical degrees of the University of London, and for the first and final F.R.C.S.Eng. examinations. Special teaching is provided to meet the requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, eight house-surgeons, sixteen assistant house-surgeons, two ophthalmic house-surgeons, two house-surgeons in the genito-urinary and orthopaedic departments, two house-physicians (children's department), two house-physicians (dermatological and neurological), and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house-surgeons, and the orthopaedic and genito-urinary house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, ear, nose, and throat, gynaecology, diseases of children, diseases of the nervous system, dermatology, actinotherapeutics, anaesthetics, orthopaedics, vaccine, tuberculosis, genito-urinary and venereal disease; clinical assistantships in the various special departments are open to post-graduates.

Scholarships, Prizes, etc.—The following scholarships in Arts and Science are awarded. A. Open Junior Scholarships: (1) An Arts Scholarship of the value of £100, (2) a Science Scholarship of the value of £100; these are awarded annually in April. (3) A War Memorial Scholarship of the value of £200, awarded alternately in Arts and Science. This scholarship is open every other year; the next award will be made in April, 1938 (in Science). B. Confined Scholarship in Science. A Junior Science Scholarship of the value of £100 is offered for competition annually to candidates who have attended the preliminary science classes at this school. This scholarship is awarded on the results of the first M.B.London Examination held in July. For the Arts Scholarship candidates must be under 19 years of age on August 1 of the year of the competition, and for the Open Junior Science Scholarship candidates must be under 20 years of age on August 1 of the year of the competition. C. University Entrance Scholarships: (1) A War Memorial Scholarship, entitling the holder to free medical education for three years; (2) an exhibition of the value of £60; both of these are awarded annually in June or July. Candidates will be examined in two of the following subjects at their option: (1) anatomy and embryology; (2) physiology; (3) pathology, including bacteriology; (4) organic chemistry. The examination is held in common with the Medical School of St. Thomas's Hospital and the Medical College of St. Bartholomew's Hospital. *Prizes:* Junior prizes for general proficiency, £20, £15, £10; Hilton Prize for dissection, £5; Michael Harris Prize for anatomy, £10; Sands-Cox Scholarship for physiology, £15 for three years (awarded triennially); Wooldridge Memorial Prize for Physiology, £10; Beaney Prize for pathology, £34; Treasurer's Medal and Prize in medicine, Treasurer's Medal and Prize in surgery, Golding-Bird Gold Medal and Scholarship for bacteriology (£29), Golding-Bird Gold Medal and Prize (£29) in obstetrics and gynaecology, Edgcumbe Prize (books to the value of £3 10s.) awarded annually to the student who is placed *proxime accessit* for the Confined Junior Science Scholarship; and the Leonard Lubbock Prize in Clinical Pathology (£10) are awarded annually after competitive examination. *Studentships:* The following studentships are open to graduates from this school. (1) Gull Studentship in pathology, of the value of £250 per annum; (2) Beaney Scholarship in materia medica, of the value of about £60; (3) Anderson Demonstratorship in clinical chemistry, value £175 per annum; (4) Arthur Durham Travelling Scholarship of £100, awarded triennially; (5) Griffiths Demonstratorship in pathology, of the value of £320 per annum; (6) Hilda and Ronald Poulton Fellowship, value £150 per annum; (7) Adrian Stokes Fellowship in pathology and bacteriology, value £200, awarded biennially.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S.E.1.

King's College Hospital

The New Medical School at Denmark Hill, opened in July, 1933, contains the museum, research laboratory, research rooms, common rooms, lecture rooms, refectory, and two squash rackets courts. Provision is made for all the subjects of the medical curriculum. The hospital was opened in 1913, and is easily reached from all parts of London. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors.

The Hall of Residence for members of the medical school is situated on Champion Hill. Both the Hall and the athletic ground are within ten minutes' walk of the school.

The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also the common rooms.

Appointments.—Thirty-one resident medical and surgical appointments are made during each year, as well as dressers and clerks in the wards, out-patient departments, post-mortem rooms, and special departments. Each of the special departments has clinical assistants. There are eight registrars and four tutors, all of whom receive salaries.

Scholarships, etc.—At entrance: Science Scholarship, £100. At commencement of Final Studies: Anatomy and Physiology Scholarship, £100; Pathology Scholarship, £100; two Raymond Gooch Scholarships, each £105; two Burney Yeo Scholarships, each £105 (for Oxford and Cambridge students); Seamen Scholarships, £50 a year; Epsom College Scholarship, £100; Senior Scholarship, £40; Todd Prize, Tanner Prize, Cheyne Prize, Legg Prize, Ware Prize, Ferrier Prize in Neurology, Class Prizes and Medals.

Fees.—The inclusive fee of £125 covers entrance and tuition fees, and subscriptions to the clubs and societies.

Dental School.—This school was opened in October, 1923, and, in conjunction with King's College, provides complete courses for dental degrees and diplomas.

The calendar of the school can be obtained on application to the Dean, John A. Drake, M.D., F.R.C.P., D.P.H., or to the Secretary of the Medical School, S. C. Ranner, M.A., King's College Hospital, Denmark Hill, S.E.5.

The London Hospital

The London Hospital serves the East End of London, and with 850 beds is the largest voluntary hospital in England. Students have the choice of five medical and five surgical firms. Each firm consists of two physicians or surgeons, a registrar, a house-physician or house-surgeon, about fifty beds, and seven clinical clerks or dressers. The number of students admitted each year is limited, so as to ensure that every student shall have an average of seven or eight beds allotted to him when acting as a clerk or dresser. The out-patient department deals with a hundred thousand new patients per annum, and is extensively used for teaching. Three wards devoted to maternity and gynaecological cases, the "*district*" served by the hospital, and the neighbouring County Council maternity centre for East London afford exceptional opportunities for gaining experience in the practice of midwifery. The size of the hospital necessitates a large number of resident medical officers. Every year seventy resident house-physicians and house-surgeons and eighty salaried non-resident clinical assistants are appointed. As the school is relatively small the chances of a student gaining some of these appointments are con-

siderable. The honorary visiting staff numbers over fifty. All take their part in teaching. The work of the hospital never stops, and at the "London" a student can gain a wealth of clinical experience and obtain a variety of clinical teaching which cannot be surpassed.

The Medical College is attached to the hospital, and is staffed by professors of anatomy, physiology, bacteriology, chemical pathology, morbid anatomy, and medicine of the University of London. Special courses in anatomy and physiology for the Primary F.R.C.S. and advanced courses in surgery for the Final F.R.C.S. examination, and in medicine for the M.D. and M.R.C.P. examinations, are held twice a year.

Scholarships and Prizes.—The following is a list of scholarships and prizes:—At entrance: Price Scholarship in science, £100. Two open scholarships, each of the value of £100. A Scholarship open to students of Oxford and Cambridge Universities: £100, anatomy and physiology; Entrance Scholarship in certain subjects of the preliminary examination in general education, £50; Epsom Scholarship, "free medical education." After entrance: Buxton Prize in anatomy and physiology, £40; Letheby Prizes in organic chemistry and chemical pathology, £25; H. L. B. Haking Prize in clinical obstetrics and gynaecology, £25; Duckworth Nelson Prize in practical medicine and surgery, £10; Hutchinson Prize in clinical surgery, £60; Treves Prize in clinical surgery, £20; Sutton Prize in pathology, £20; Sir Andrew Clark Prize in clinical medicine and pathology, £14; T. A. M. Ross (*prox. acc.*) Prize in clinical medicine and pathology, £10 10s.; Anderson Prizes in elementary clinical medicine, £20; Dressers' Prizes, £20; the F. N. Charrington Prizes in practical anatomy, £20; Arnold-Thompson Prize in medical and surgical diseases of children, £15; Liddle Prize, £120; Francis Farmer Entrance Scholarship in biology, chemistry, and physics, £25; Harold Fink Prize in dental surgery, £8 8s.; The "London" Prize in dental prosthesis, £6 6s. Six class examination prizes of the value of £3 3s. to £5 5s. are offered for competition at the end of the courses of lectures in the dental curricula. Funds to the value of over £113,000 permit of financial assistance being given to students and graduates engaged in medical research.

The Medical College contains a modern museum of pathology and a library provided with all the current medical periodicals in charge of a full-time librarian. There is also an Athenaeum Club and dining hall, a gymnasium, a fives court, and two squash courts in the students' hostel. The athletic ground of 13 acres at Hale End is within easy distance of the hospital. Although situated in the East End the hospital is only twenty minutes from Charing Cross and Baker Street. There is accommodation for sixty students in the students' hostel.

Further details may be obtained from the Dean, Dr. A. E. Clark-Kennedy, F.R.C.P., physician to the hospital, who is always pleased to meet students wishing to see the hospital and college. Application for admission should be made to the *Dean, Turner Street, London, E.1.*

The Middlesex Hospital

The school and hospital are in Mortimer Street, W.1, close to Oxford Circus, Goodge Street, and Great Portland Street stations. There are a gymnasium, squash rackets court, common rooms, and restaurant within the hospital precincts, and an athletic ground within easy reach. The hospital contains 590 beds, including a wing containing beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for neurological cases, for cases of venereal disease, for diseases of children and of the skin and eye, for ear, nose, and throat cases, and for dental cases. The hospital has been entirely rebuilt, and includes a new house for resident officers.

The medical school, which includes the Bland-Sutton Institute of Pathology, the S. A. Courtauld Institute of Biochemistry, the Barnato-Joel Laboratories, and the Ferens Institute of Otology, is completely equipped for teaching the entire medical curriculum, including the pre-medical subjects, chemistry, physics, and biology. The Bland-Sutton Institute, under the direction of the Professor of Pathology, contains large pathological laboratories, and smaller rooms for original investigation, as well as a pathological and anatomical museum. Bacteriological and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Junior assistants in the pathological and bacteriological laboratories are elected annually from recently qualified students. Every facility is given for original research. The Biochemical Institute is under the charge of the Professor of Biochemistry, and contains teaching and research laboratories in addition to those devoted to the routine chemical pathological work of the hospital. The Barnato-Joel Laboratories offer unrivalled opportunities for the study of cancer in both its clinical and its pathological aspects.

Appointments.—Thirty-five resident appointments are open annually for competition among students of the hospital. The officers, and four resident officers to the special departments expense. Three casualty medical and two casualty surgical officers, and four resident officers to the special departments are appointed annually. Eight house-surgeons are appointed every year at intervals, after examination; eight house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months, and two orthopaedic house-surgeons and one senior and two junior resident assistant anaesthetists are appointed annually. A dental house-surgeon is appointed every eight months. Eleven registrars, each at a salary of £300 per annum, are appointed annually, and one half-time dental registrar at £150. In the out-patient departments and wards the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk or dresser to the department for diseases of the skin and nerves, for diseases of women, for diseases of the ear, nose, and throat, for diseases of the eye, and to the departments for orthopaedics and for odontology. Extern midwifery clerks and post-mortem clerks are also appointed; every student secures six months' experience in midwifery and gynaecology without leaving London. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Non-resident qualified clinical assistants are appointed to the medical and surgical departments and also to the following departments: neurology, ophthalmology, otology, odontology, children, and electrotherapeutics.

Scholarships.—There are two open Entrance Scholarships, value £100 each. Two scholarships, of the value of £100 each, for students of the Universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology. Students joining the school in the previous April are eligible. In addition, there are two scholarships, value £100 each, open to students of the school when they have passed in anatomy and physiology. The Freer Lucas Scholarship is annually awarded on the nomination of the Head Master to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Broderip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25; Hetley Clinical Prize, value £25; James Kingston Fowler Prize, value £15 15s.; Leopold Hudson Prize, value 11 guineas; and the Colin Mackenzie Prize, value 10 guineas.

The rebuilding of the hospital has been completed.

Fees.—(*a*) Entrance fee, 25 guineas, payable on joining the medical school; Pre-medical students: For one year or less, £21. (*b*) Students who have completed the Preliminary Science course: Five annual fees of £45. The annual fee for further attendance at the medical school, if a registrable qualification has not been obtained, is £23. (*c*) Oxford and Cambridge and other students who have completed the Intermediate course: entrance fee, 15 guineas; three annual fees of £45; further annual fees as above. These fees are inclusive and cover the cost of instruction in vaccination, fevers, etc., and also the subscription to the amalgamated clubs and hospital journal.

Further information may be obtained from the Dean or the School Secretary.

St. Bartholomew's Hospital

This institution fills one side of Smithfield and Giltspur Street, covering the greater part of a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 762 beds. Extensive buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The old medical school buildings have at their side a very large building, which includes quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to an extensive post-mortem room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. A new block of surgical wards and five operation theatres (one attached to each surgical unit), with accommodation for 250 patients, was opened in June, 1930. A similar new block of medical wards, erected on the site of the old *South Block*, was opened by H.M. Queen Mary in July, 1937. One of the old blocks previously used for surgical cases has been reconverted for the housing of an enlarged gynaecological and obstetrical unit, with separate operation theatres attached. The Students' Union Athletic Ground, seventeen acres in extent, is situated on the Foxbury Estate at Chislehurst, and is easily accessible from the hospital.

The Medical College has recently purchased the site and buildings in Charterhouse Square (five minutes' walk from the hospital), formerly occupied by the Merchant Taylors' School, and the whole of the pre-clinical departments have now been transferred there. Various athletic amenities, including squash racket courts, are available on this new site.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B., M.D. of the Universities of Oxford, Cambridge, and London, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.Chir. Cantab., M.S.Lond., and F.R.C.S.Eng.

Clinical Units.—Special clinical units have been established in medicine and surgery, each under the charge of a professor and director, who devotes the whole of his time to the purpose of hospital practice, teaching, and research. In each unit there are an assistant director and four assistants, for whom special laboratory accommodation has been provided by a gift from the Sir William Dunn Trustees. The appointments of clerks and dressers in these departments are open to all students, and, so far as possible, arrangements are made for all students to study in these units during a part of their clinical course.

Appointments.—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (ophthalmic, orthopaedic, gynaecological, children's laryngological, aural, dermatological, venereal, electrical, and dental), and in the post-mortem room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical, and in special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "junior" house-physicians and house-surgeons, and receive a salary of £80 a year. During their second six months they become "senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed—the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum—and all are provided with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. In the selection of men for these posts preference is given to those who hold the medical degrees of Oxford, Cambridge, or London.

Scholarships.—Seven Entrance Scholarships and Exhibitions are awarded annually. The subjects of examination and conditions of eligibility for these scholarships are: (1) and (2) one scholarship, entitling the holder to free undergraduate medical education for a period of three years, and one exhibition, value £60, in any two of the following subjects: human anatomy and embryology, physiology, pathology (including bacteriology), biochemistry. Candidates must have completed their examinations in anatomy and physiology in a British school or university outside the London Metropolitan area. (3) One scholarship, value £100, in the three following subjects: chemistry, physics, biology; limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (4) An entrance scholarship in arts, of the value of £100, in mathematics; Latin or Greek or French or German; a second language or chemistry or physics. (5) The Jeaffreson Exhibition in the same subjects as No. 4, of the value of £50. Candidates for Nos. 4 and 5 must be under 19 years of age. (6) Helen Cave Memorial Scholarship, awarded after open competition to sons of registered medical practitioners, value about £200, conditions obtainable from the Dean. (7) The Shuter Scholarship, value £50, in anatomy and physiology, is confined to Cambridge graduates. The total value of the scholarships and prizes is about £1,900 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

St. George's Hospital

This School is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at King's College in the Strand. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

Appointments.—Eight casualty officers, ten house-surgeons, and eight house-physicians are appointed annually. They are provided with board and lodging in the hospital, and receive honorariums of £40 per annum. In addition, the following appointments are open to all qualified students of the hospital: assistant resident physician at £250 per annum; two surgical chief assistants at £200 per annum; medical officer to the Atkinson Morley Convalescent Hospital at £300 per annum; two medical registrarships at £100 per annum; medical officer to the biochemical department at £100 per annum; assistant curatorship of the museum, £100 per annum; obstetric assistantship, resident, at £100 per annum; the post of resident anaesthetist at £100 per annum.

Scholarships.—The following Entrance Scholarships and Exhibitions in anatomy and physiology and in general pathology are awarded in July to candidates who have passed the second M.B.London or corresponding examination; Senior William Brown Exhibition of the value of £120; Junior William Brown Exhibition of the value of £80; Anne Selina Fernee Scholarships (two) of the value of £80 each; Anne Selina Fernee Exhibitions (two) of the value of £60; Devitt-Pendlebury Scholarship of the value of £50; and Exhibitions,

each of the value of £40 and up to four in number. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees.—For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £42. No entrance fee is payable by St. George's students who have studied at King's College.

Further information may be obtained from the Dean of the Medical School.

St. Mary's Hospital

St. Mary's is exceptional in its situation, for while it is adjacent to a large poor district in which it serves some 500,000 persons, one-tenth of whom (on an average) pass through the hospital annually for treatment of one kind or another, it is, nevertheless, so near to Kensington Gardens and one of the best residential districts of London that it offers to the medical student the unusual possibility of living in close touch with his work, without a wearisome journey in an overcrowded train or tube. As a direct outcome of this, social life among students is closer than is possible where the members of a school live scattered in many parts of London and its suburbs.

Approximately £250,000 has been spent in rebuilding the medical school and laboratories upon a site adjoining the hospital. The new buildings were formally opened by his late Majesty King George V, accompanied by Queen Mary. Apart from the laboratories, class-rooms, and theatres for all the subjects in the curriculum, they include a library, restaurant, students' club, billiard room, full-sized swimming bath, squash rackets court, gymnasium, boxing ring, and an underground garage for fifty cars.

The principle underlying the clinical teaching is to encourage the student, under supervision, to carry out for himself the various methods of clinical investigation and treatment. This is secured by the provision of a very large number of appointments, and by developing the system of clinical clerkships and assistants. Large classes are avoided whenever possible, and the intimate association between staff and student has been reinforced by the institution of Clinical Units. St. Mary's is one of the three medical schools in London to enjoy the great advantages in teaching and research which these units confer. The clinical material is exceptional. A new block has recently been added containing two operating theatres and 60 beds. Owing to affiliation with adjacent hospitals, more than 1,000 beds are now available for teaching. There are lying-in beds at St. Mary's, with upwards of 500 confinements yearly, and in addition to the instruction thus obtained each student is sent (without further fee) to Queen Charlotte's Hospital for a fortnight as part of his training in midwifery.

Students especially interested in pathology and bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright. Two Research Studentships of £200 each are awarded annually.

From three to five Entrance Scholarships are awarded annually by nomination. Full particulars may be obtained from the School Secretary, St. Mary's Hospital, Paddington, W.2. Numerous appointments are open to newly qualified members of the medical school, including seventeen salaried posts with salaries varying up to £750 per annum.

The Old Merchant Taylors' ground (13 acres) has been acquired. On sand, it remains dry throughout the winter.

St. Thomas's Hospital

The Hospital and Medical School are situated along the Albert Embankment between Westminster and Lambeth Bridges. The buildings form one of the most striking architectural features of London, opposite the Houses of Parliament, with Lambeth Palace and the beautiful grounds adjoining immediately to the East.

The hospital consists of eight linked-up pavilions, the Medical School buildings being separated from the hospital by a quadrangle; they comprise a magnificent Department of Anatomy with its own lecture theatre, museums, research laboratory, and *x*-ray department, the School of Physiology, named after Sir Charles Sherrington, O.M., completely equipped for teaching and research, a newly rebuilt Department of Chemistry with special facilities for research; Physics and Biology Laboratories. The school buildings contain also the library and reading room, which overlook the river and contain approximately 8,000 volumes, also an excellent supply of periodical literature adapted to the needs of medical students and research workers. The Museum, named after Professor S. G. Shattock, is also situated in the School; it contains nearly 5,000 preparations. In the west wing are the Pathological Institute and the Photographic Department. The post-mortem room was entirely rebuilt in 1932; it is a model of its kind, with a large demonstration amphitheatre, which is perfectly adapted for teaching purposes and for the intimate study of morbid pathology.

The complete curriculum is provided for; students can join the Medical School directly after passing the requisite examination in general education, and proceed at once to the study of the first M.B. pre-medical subjects, which are taught by experienced professors and lecturers with the assistance of full-time demonstrators. Most students, particularly those entering for the first M.B. pre-medical examination, enter in October, but the clinical studies are arranged in three-monthly periods, and students can join at any time of the year for clinical studies. Classes for the Primary F.R.C.S. are held before each examination; these classes are held in conjunction with St. Bartholomew's and Guy's, three to four weeks' special teaching being arranged by each of the three Schools in turn. Instruction in the psychology of the normal is given during the later periods of pre-clinical studies. Classes in pharmacology and materia medica and pharmacy cover the requirements of all the examining bodies.

Clinical Studies.—The hospital contains 640 beds; in addition it has 30 beds (with teaching facilities over a further 150) at the Pyrford Orthopaedic Hospital, and 22 beds at the St. Thomas's Babies' Hostel in Lambeth. During 1935 the number of patients admitted into the hospital was 11,814; during the same period 99,341 out-patients were treated. In the Maternity Department 2,238 women attended; 643 were admitted into the special maternity ward and 383 were delivered in the district. Casualties to the number of 147,213 attendances were dealt with during the same period. In addition to the 692 beds actually controlled by the hospital, students have the advantage of a close liaison with Lambeth Hospital, where demonstrations of rare and advanced cases, such as are seldom seen in the wards of a general hospital, are arranged at regular and frequent intervals by the superintendent. The obstetric training of students is supplemented by an arrangement with St. James's Hospital, Balham, whereby throughout the year two students at a time spend a fortnight in residence at St. James's Hospital, where they follow, and take part in, the maternity work of the hospital. Clinical teaching of medicine and surgery is carried out daily throughout the year in the wards and out-patient departments. From the day that a student enters on his clinical studies he comes into direct responsible contact with patients. Every student acts as clerk in the post-mortem room and in the pathological laboratories. The Medical Unit, through which every student passes for a period of three months, provides a very thorough grounding in clinical medicine and clinical biochemistry, the in-patient clerking being afterwards completed under the aegis of a different medical firm. In addition to three months' dressing in the casualty department at the outset of his clinical studies, every student becomes, for six months, a dresser to one of the surgeons of the hospital; during this period he receives instruction in anaesthetics. Great stress is laid on the teaching of pathology, which proceeds *pari passu* with the clinical appointments held by the student throughout the curriculum. The special maternity ward in the hospital gives the student scope for elementary obstetric training before he takes his turn of duty on the district, where again he works

under close supervision. All the special departments are available for the teaching of students; special attention is given to ante-natal instruction and the teaching of the diseases of children, a department through which every student passes. The laboratories and reading room in the units building are open day and night for those who wish to avail themselves of these facilities. A special Tuberculosis Department in the hospital forms a part of the Lambeth scheme for the treatment of patients. The Venereal Disease Department is part of the L.C.C. scheme. The clinical material in the hospital is placed wholly at the disposal of undergraduate students with the exception of a small class held twice yearly for the Final F.R.C.S. Examination; postgraduate clinical students are not accepted. Special tutorial classes in all subjects are held before all the final examinations of the Universities and Conjoint Board.

St. Thomas's House—the Amalgamated Students Clubs' premises immediately opposite the hospital—was opened in 1927; it has all club amenities, with two squash rackets courts, a miniature rifle range, and ample garage accommodation. The hostel in the same building has accommodation, with all modern comforts, for 50 resident students. There is a hard tennis court in the Medical School quadrangle, and the beautiful sports ground at Chiswick provides for all field games.

Appointments.—Following qualification the following appointments are open to students: twenty-five clinical assistantships to the various special departments are appointed every three months. Eight resident casualty officers and anaesthetists, seven house-physicians, and nine house-surgeons are appointed every six months. Nine chief assistants (unpaid) to the special departments and nine non-resident registrars (medical, surgical, obstetric, and ophthalmic) at a salary of £250 hold appointments renewable yearly. A resident anaesthetist (salary £200), a resident assistant physician, and a resident assistant surgeon (salary £225 per annum) are appointed annually. Assistants in the medical and surgical units (salary £450 to £600) hold appointments with a maximum tenure of four years. Three assistants in the Department of Pathology hold appointments at a salary of £450 to £600 a year.

Scholarships and Prizes.—At this School there are the following Entrance Scholarships: Two in Natural Science, of the value of £150 and £60 respectively; the University Scholarship of £100 in any two of the following: anatomy, physiology, pathology, chemistry, also the "Hector Mackenzie" University Exhibition of the value of £60. The value of all Entrance Scholarships is taken out in Tuition Fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students £25; (*b*) and (*c*) Musgrove Scholarship or (alternatively) Peacock Scholarship each for third-year students and tenable for two years £35 each; (*d*) Mead Medal, medicine, pathology, and hygiene; (*e*) Wainwright Prize, medicine; (*f*) Toller Prize, medicine; (*g*) Cheselden Medal, surgery and anatomy; (*h*) Clutton Memorial Medal in Clinical Surgery, biennial; (*i*) Beaney Scholarship £50, biennially, surgery and surgical pathology; (*j*) Solly Medal and Prize, biennial, reports of cases; (*k*) Sutton Sams Prize, biennial, reports of cases; (*l*) Bristowe Medal, pathology and morbid anatomy; (*m*) Hadden Prize, pathology and morbid anatomy; (*n*) Grainger Testimonial Prize £31 10s., anatomy and physiology; (*o*) Louis Jenner Research Scholarship tenable for two years, £60 annually, pathology; Anderson Scholarship and Perkins Fellowship, research; Myers Exhibition and Planck Prize in Psychological Medicine; and others, the result of special donations and bequests are available during the academic year.

University College Hospital

The school, which forms part of the corporation of University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine, surgery, midwifery and gynaecology, pathology including morbid anatomy, chemical pathology, biochemistry and bacteriology, cardiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electrotherapeutics, and skiagraphy. The hospital and school have acquired the National Dental Hospital and College as their dental departments, thus providing every facility for the study of dental subjects. The Royal Ear Hospital has also been amalgamated as the Ear, Nose, and Throat Department, and a new hospital for in- and out-patients, close to University College Hospital. It contains 41 beds, including eight private wards for patients of limited means.

The school thus provides the final course of study for the degrees of the Universities of Oxford, Cambridge, London, Durham, and other British universities, and for the diplomas of the Royal Colleges of Physicians and Surgeons in medicine and in dental surgery. Each department is also equipped for more advanced work, and provides facilities for research.

Clinical units in medicine, surgery, and obstetric medicine are in operation. The whole-time directors of the units are concerned with the organization of the teaching generally, but the honorary staff is responsible for the largest share of the teaching in the wards and out-patient department of the hospital. The hospital has 617 beds, including eighty-five in the obstetric hospital and seventy-seven in the new private patients' wing.

The new buildings of the obstetric hospital of eighty-five beds (rendered possible by the Rockefeller benefaction), the new Residents' House (with accommodation for thirty-three residents and students), the extension of the Nurses' Home, and the new research laboratories for the Medical School, are now finished and in full occupation. Among the most recent developments are the following: (i) The new Private Patients' Wing with seventy-seven beds, all of which are in single rooms with the exception of two four-bed wards. This wing has the very latest medical equipment, together with all possible devices for the comfort of patients. (ii) An entirely new and up-to-date *x*-ray diagnostic department. (iii) New ante-natal, gynaecological, and child welfare out-patient departments. The opportunity has been taken to transfer the present children's out-patient department to the new extension, thus securing the obvious advantage of easier co-operation.

A Students' Hostel adjoins the Medical School. Large, airy, and handsomely furnished bed-sitting rooms, each fitted with hot and cold running water, are available.

Appointments.—The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, medical registrars, surgical registrars, obstetric registrar, Harker Smith radium registrar, ophthalmic registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, skin and venereal diseases departments, and house anaesthetists.

Scholarships.—The following scholarships and prizes are open to competition: Two Goldsmid Entrance Scholarships entitling the holder to the final course of medical study; one Goldsmid Entrance Exhibition entitling the holder to a reduction by £80 of the fees due for the full course of final medical study; and a Filliter Entrance Scholarship in pathology, entitling the holder to a reduction by £52 10s. of the fees due for the full course of final medical study. The examination for these scholarships is in any two of the following subjects: anatomy, physiology, general pathology, and biochemistry. The examination for 1938 will be held as follows: Monday, July 18, 10 a.m. to 1 p.m., anatomy; 2 p.m. to 5 p.m., physiology. Tuesday, July 19, 10 a.m. to 1 p.m., biochemistry; 2 p.m. to 5 p.m., general pathology. Candidates for the Filliter Exhibition need take pathology alone. Radcliffe Crocker Travelling Scholarship in dermatology for one year, value about £280; the Graham Scholarship in pathology of a sum not exceeding £400 per annum; Leslie Pearce Gould Research Scholarships in surgery for one year, value about £260; the Bilton Pollard Fellowship of the annual value of £650 per annum; the Atkinson Morley Scholarship of £45 a year for three years awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies; the Magrath Clinical Scholarship, value about £160; Ferriere Scholarship, value £25; the Filliter Exhibition in pathology of £30; the Percival Alleyn Prize for the advancement of surgery by research, value about £300 and awarded every three years; the Graham Gold Medal for research work; four Fellows Medals in clinical medicine; Liston Medals in clinical surgery;

the Bruce Medal in pathology and surgery; two Tuke Medals in pathology; the Erichsen Prize for practical surgery; and the Roberts and Suckling Prizes in obstetrics and gynaecology.

Fees.—Inclusive fee to cover complete clinical course: £45 per annum for three years. Oxford and Cambridge students who have completed their course in pathology: £40 per annum for three years. There are no extras, as these fees include courses of instruction in pharmacy, vaccination, and fevers, and life subscription to the Medical Society or Women's Medical Club.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street, W.C.1.

Westminster Hospital

The school, with its hospital situate in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College, Strand, and University College. The rest of the work is done in the school buildings near the hospital. There is at present being erected a new Hospital and Medical School on adjoining sites in Horseferry Road (five minutes from the present site). The new school buildings will be ready for occupation in the early part of 1938 and the new Hospital a year later. The new buildings will incorporate the latest advances in medical science. The number of in-patients averages 5,000 and out-patients upwards of 30,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery. Every student must perform the duties of out-patient dresser for three months, and afterwards hold the office of in-patient dresser for three months. He is also required to serve two terms of three months each as medical clinical clerk to the in-patient physician, and one term as gynaecological clinical clerk. Pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has completed his examination in anatomy and physiology. Clerks and dressers in the special departments of hospital practice are periodically appointed.

An annexe devoted to radium therapy and research, containing twenty-two beds, has recently been opened.

The athletic ground is situated at Tooting, and can be reached in twenty minutes from the hospital.

Appointments.—A medical registrar and an assistant medical registrar at a salary of £250 and £150 and three surgical registrars at a salary of £250 are appointed annually, and an obstetric registrar with a salary of £50 plus £50 for tutorial fees. A senior resident and casualty officer, salary £104 per annum and board, appointed for six months, may be extended for a further period of six months. A medical registrar to the children (Wander scholar), salary £250, is appointed for one year. Three house-physicians, three house-surgeons, three assistant house-physicians, three assistant house-surgeons, and a resident obstetric assistant are appointed after examination, and are provided with rooms, commons, and salary of £52 per annum, except the assistant house-physicians and the assistant house-surgeons, who are provided with commons only. The assistant house-physicians, after three months' service, become house-physicians for a further period of six months, and the assistant house-surgeons, after three months' service, become house-surgeons for a further period of six months. One house-anaesthetist is appointed for six months, non-resident, salary £100 per annum. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among the qualified students.

Scholarships.—The following open scholarships are offered for competition during the year 1936–7. In the winter session two scholarships in anatomy and physiology, £75 each. In the spring two scholarships in anatomy and physiology, £75 each. In May an examination in English Essay, Chemistry, and Physics is held, on the results of which four Entrance Scholarships to the value of £75 each are awarded.

During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine (Reports on Cases); Chadwick Clinical Surgery Prize (Reports on Cases); Chadwick Prize (Medicine and Surgery); Frederic Bird Medal and Prize; Abrahams Prize (Clinical Pathology); Hanbury Prize in Diseases of Children; Sturges Class Prize in Bacteriology; Class Prize in Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine, Public Health, and Surgery.

Fees.—The annual composition fee is 40 guineas. At entrance fee is payable by all students—namely, primary and intermediate students, £10 10s.; students entering for the final subjects only, £8 8s. These fees, which include subscriptions for membership of the Clubs Union, are subject to alteration from time to time as the School of Medicine may direct.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital Medical School, 12, Caxton Street, Westminster, S.W.1.

London (Royal Free Hospital) School of Medicine for Women

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of the University of London. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large, well-equipped library, common room, Union Room, and refectory are provided for the use of students. Resident accommodation for 80 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 326 beds, of which 20 are for private patients. The obstetrical and gynaecological unit controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear, and skin, children and infant welfare, venereal diseases, orthopaedic surgery, massage, light, electrical and *x*-ray work, dentistry, and casualty. Students attend the practice of one of the fever hospitals of the London County Council and receive special instruction in psychological medicine at Horton Hospital, Epsom; they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, Great Ormond Street, the National Hospital for Nervous Diseases, the South London Hospital, the Central London Ophthalmic Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination.

Appointments.—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne and A. M. Bird Entrance Scholarships, value £30 a year for six years, the St. Dunstan's Medical Exhibition, value £60 a year for three years, which may be extended to five years, the Alfred Langton Scholarship of £35 a year for two years, the Flora Murray Bursary of £50, the Mabel Sharman-Crawford Scholarship, value £20 a year for four years, and the Emma Beilby Bursary of £55 a year, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship and the MacIntyre Evans Scholarship each of the value of £75 a year for four years; the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years; the Dr. Margaret Todd Scholarship of the value of £37 10s. a year for four years; and the Sarah Holborn Scholarship of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The School Jubilee Bursary of £50 a year for three years is offered every third year. The Fanny Butler Scholarship of £16 a year for four years is awarded every fourth year. The Bostock Scholarship, value £90 a year for five years, is awarded by the University of London on the recommendation

of the Reid Trustees and the School Council on the result of an examination held in May every fifth year. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, of the value of £25 a year for four years, is awarded every fourth year. The A. M. Bird Clinical Scholarship of £30 a year for three years. The John Byron Bursary of £20 a year for two years, the Julia Ann Hornblower Cock Prize of £60, the Helen Prideaux Prize of £60, the Mabel Webb and A. M. Bird Research Scholarship of £200 for one year, the A. M. Bird Postgraduate Scholarship of £200 for one year, together with other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Phipson Postgraduate Scholarship of £95 is awarded annually. Altogether the school offers annually £2,050 in scholarships. Missionary societies offer scholarships on certain conditions to assist women who wish to work in the Mission Field.

Fees.—For the full course of study: £50 per annum throughout the course.

The Students' Union exists to promote corporate action of the students on matters of common interest, to promote and maintain athletic and other clubs, and to issue a school magazine. All students are required to become members of the Union.

Further information can be obtained from the Warden and Secretary.

King's College

The Medical Faculty at this College of the University of London gives instruction in the subjects of medical science for all the usual preliminary and intermediate examinations in medicine, surgery, and dentistry. For final studies students proceed to one of the associated hospitals —King's College, Charing Cross, St. George's, Westminster —whose ample facilities, including over 1,000 beds, are available for clinical work.

The Medical Faculty of the College provides a general university education in touch with other faculties, classes of which medical students are permitted to attend. There are many college societies, clubs, and functions in which students of all faculties have opportunity of meeting each other. The College has a large athletic ground at Mitcham, and well equipped with a new pavilion.

The first-year subjects are taught in the large departments of the Faculty of Science. Within the last few years there has been complete remodelling of the second and third year medical departments at a cost of £70,000. This has comprised a new Department of Anatomy and reorganization, with considerable extension, of the Department of Physiology.

Scholarships.—The scholarships include: (1) Two Warneford Entrance Scholarships, each £30 for four years; subjects—selected from mathematics, classics, divinity, and science. (2) One Sambrook Entrance Scholarship of £30 for three years; subjects of examination selected from mathematics, classics, and science. One Warneford Scholarship awarded at end of first year. Subjects as for First M.B. together with Divinity. (3) Worsley, £100, paid in five annual instalments. The holders of the preceding awards must proceed to King's College Hospital. (4) Rabbeth Scholarships, value £30 and £15, in July, for the best student of the first year. (5) Daniell Scholarship, £40. (6) The Layton and Berridge Studentships, each £150 and £100 per annum respectively, and (7) numerous prizes.

Full information as to admission, fees, and scholarships can be obtained from the Dean of the Faculty of Medical Science, King's College, Strand, W.C.2.

University College

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy (including embryology and histology), physiology, biochemistry, and pharmacology. The anatomy building, provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31, 1923, by His Majesty King George V. This building forms part of the block which includes physiology and pharmacology. A new building has recently been added for the department of zoology, for the endowment and equipment of which the Rockefeller Foundation has made another generous benefaction. Research work is undertaken in all the above-named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society, with use of the College gymnasium and the athletic grounds. There is also a collegiate residence for about sixty-seven men students at Ealing and for one hundred and seventy-two women students in Malet Street.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 160 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School)—the examination includes an English essay; two Entrance Exhibitions in the same subjects, each of the value of 55 guineas; a Faculty of Medical Sciences Entrance Scholarship, value £30 a year, for three years; the Bayliss-Starling Memorial Scholarship (physiology and/or biochemistry), £120; and the Ferriere Scholarship, £25, tenable for three years at University College Hospital Medical School.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and both parts of the Second Examination, and for the corresponding examinations held by the Conjoint Board in England, amount to 118 guineas. These fees do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Gower Street, London, W.C.1.

THE PROVINCES

There are in England and Wales, not counting London, ten medical schools, each supplying instruction in the full medical curriculum. Accounts of them here follow. In several cases information is appended about hospitals other than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or postgraduate study.

Oxford and Cambridge

At both Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them; but this is not commonly done, and is never, in the ordinary way, advised by the university medical authorities. The local hospitals—the Radcliffe Infirmary at Oxford and Addenbrooke's Hospital at Cambridge—though well equipped, are comparatively small. Students are therefore encouraged, as soon as they have completed the earlier examinations and taken a degree in arts, to join one of the London medical schools, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students take

the London Conjoint diplomas before graduating in medicine and surgery at their own university. The experience gained by holding resident hospital appointments is naturally of much advantage when sitting for the Final M.B. examination.

Birmingham

The school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessaries devoted to their use by the university. The clinical work is done at the Birmingham United Hospital (General and Queen's Hospitals), which are amalgamated for the purpose. Together they have upwards of 800 beds for medical, surgical, and special cases, with an array of special departments of all kinds, including one for lying-in women (about 13,000 in-patients and 90,000 out-patients). Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures are delivered weekly throughout the session. Special tutorial classes are also held alike for the degrees of Birmingham and other universities, and for the diplomas of corporations.

The Birmingham United Hospital.—The practices of the General Hospital and the Queen's Hospital are amalgamated for the purpose of clinical instruction, which is carried on under the direction of the Board of Clinical Studies. They present an almost unrivalled field for clinical work, possessing more than 800 beds, treating annually about 14,000 in-patients and 90,000 out-patients, and as students spend part of their curriculum in each hospital, they have every opportunity of acquiring a varied, full, and practical knowledge of their professional work. The curriculum is adapted in the first place to meet the needs of the students of the Birmingham University proceeding to the M.B., Ch.B. degrees, but it is also well adapted to the requirements of students preparing for the examinations of all other universities and licensing bodies. The advantages that the combined hospitals offer to students do not cease with graduation, for there is probably no city in which students after qualification have a larger number of resident posts open to them.

Resident posts are also available at the Children's Hospital, the City General Hospitals, the City Public Assistance Institutions, the Birmingham Mental Hospitals and Mental Deficiency Act Institutions, the City Infectious Diseases Hospitals, the Birmingham General and Branch Dispensaries, the Birmingham and Midland Eye Hospital, the Royal Cripples Hospital, the Ear and Throat Hospital, the Maternity Hospital, the Women's Hospital, at St. Chad's Hospital, Edgbaston, and at the Birmingham and Midland Hospital for Nervous Diseases. Besides positions in institutions in the City of Birmingham, there are numerous resident salaried appointments in the hospitals in the immediate vicinity which are open to the students of the Birmingham Medical School. Appointments are also open to medical practitioners in the Naval, Military, Air Force, and Indian and Colonial Medical Services.

Scholarships and Prizes.—There are numerous money and other awards for students of sufficient merit, among them being the following: Frank Fletcher and Catherine Fletcher Scholarships (not less than two per annum), tenable for five years, each of the annual value of £100, awarded on higher school certificate examination of the Joint Matriculation Board; the Walter Myers Travelling Studentship of £300, offered each alternate year for research work and tenable abroad; the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on higher school certificate examination of the Joint Matriculation Board (July)); four Queen's Scholarships of £10 10s. each, awarded annually at the second (Part II), third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men; the Ingleby Scholarships (two) of £10 for proficiency in midwifery and diseases of women; the Arthur Foxwell Memorial Gold Medal (clinical medicine); the Sampson Gamgee Memorial Medal for surgery (Final M.B.); the Russell Memorial Prize (for examination in nervous diseases, final year); the Priestly Smith Prize in ophthalmology, value about £6 (awarded in the final examination); the Peter Thomson Prize in anatomy (value about £6) for students in their third university year; the Bertram Windle Prize (value about £10) for special work in anatomy; and the John Barritt Melson Gold Medal in Physiology for students in their third university year. The Leith-Newman Prize in Pathology (Medical) (value £10) is awarded annually on students' class Leith-Newman work and professional examination, and a prize (value £5) under similar conditions for dental students. There is also a scholarship of £46 17s. 6d. for students proceeding to a degree in dental surgery. Board of Clinical Studies Prizes are awarded annually as follows: Senior Medical Prize, gold medal; Senior Surgical Prize, gold medal; Midwifery Prize, gold medal; Junior Medical Prize, silver medal; Junior Surgical Prize, silver medal.

Fees.—The composition fee for university classes is £106 5s. This covers all the work required for the degrees of Birmingham and some other universities and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine, and some other special work. The total cost for the six years' curriculum, including hospital and examination fees, is £246 0s. 6d. (If first-year science subjects are excluded, £208 15s. 6d.)

Other information should be sought from the Registrar, or the Dean of the Faculty of Medicine, The University, Edmund Street, Birmingham.

Bristol

The school is carried on by the Faculty of Medicine of the University, and provides full instruction for all its degrees and for the diploma in dental surgery.

Clinical Instruction.—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them more than 700 beds and extensive out-patient departments, special clinics for diseases of women and children, including ante-natal and post-natal work, also for eye, ear, nose, and throat, and skin diseases, in addition to large and well-equipped departments for dental work and large outdoor maternity departments. At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and biochemistry, in which special instruction is given in these subjects. Departments are provided and well equipped for radiology, radiotherapy, actinotherapy, electrotherapy, and massage, with all forms of physiotherapy. These hospitals include a National Radium Centre. The students of the school also attend the City and County Mental Hospital, the Ham Green Hospital for instruction in fevers and tuberculosis, the practice of the Royal Hospital for Sick Children and Women, containing 120 beds, and that of the Bristol Eye Hospital, with 82 beds. In addition, by the kind permission of the Health Committee of the Bristol City Council, students may attend the clinical practice at Southmead Hospital, and may complete under certain conditions their practical work in obstetrics at that institution, which has 510 beds. The Orthopaedic Hospital at Winford and Stoke Park Colony for Mental Defectives are also available.

Appointments.—(1) Undergraduate: Medical clerkships, surgical dresserships, also ophthalmic, obstetric, pathological, dermatological, ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. Clerkships are tenable at the Children's Hospital. (2) Postgraduate: at the Bristol Royal Infirmary: four house-surgeons, one casualty house-surgeon, three house-physicians, one resident obstetric officer, one gynaecological and dermatological house-surgeon, one ear, nose, and throat house-surgeon, one assistant house-surgeon (who also acts in the ophthalmic department), one dental house-surgeon, and one unpaid assistant (usually a resident student) to the senior resident medical officer. All these appointments are for six months. Salary in each case at the rate of £60 per annum, with board, apartments, and laundry, except the casualty house-surgeon and the dental house-surgeon, who receive £80

per annum. In each case the salary is increased by £40 per annum if the officer is re-elected for another six months. From the resident medical officers a senior resident medical officer is appointed at a salary of £200 per annum. Clinical assistantships in all departments are open to senior qualified practitioners. At the Bristol General Hospital: senior resident medical officer, £200 per annum; casualty house-surgeon, £100 per annum; two house-physicians, £80 per annum; three house-surgeons, £80 per annum; resident obstetric officer, £80 per annum; house-surgeon to special departments, £80 per annum. All the £80 appointments carry a salary of £100 for residents who have previously held another of them; the dental house-surgeon (non-resident), £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years. Clinical assistantships in the out-patient departments are also available.

Scholarships.—The following are among the scholarships and other awards open to students of the school: The Miriam Badock of the value of £120, and the H. H. Wills Science Scholarships, open to boys proceeding from Clifton College; the Harold Greenwood Memorial Scholarship of the value of £20, open to boys who have received instruction at State-provided schools in Clevedon (or elsewhere in Somerset) and subsequently at secondary schools in Somerset or Bristol; the Dulverton Scholarship (£100 a year for three years) has been assigned to the Medical Faculty for the year 1938; the Ashworth Hallett Scholarship, value £40, open to women only; two Martyn Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 7 guineas, for proficiency in practical surgery; the Committees' Gold and Silver Medals for fifth or sixth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in obstetrics and gynaecology; the Crosby Leonard Prize, value 6 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Royal Infirmary Faculty Prize, value £20, for general proficiency; the Sanders Scholarship, value £22 10s., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose and throat, value £24, open to men only; Lady Haberfield Scholarship, value about 25 guineas; Bristol and Bath City Scholarships and the Scholarships offered by the counties of Gloucestershire, Somerset, Wilts, Dorset, etc., are tenable in the university.

One or more Fellowships of not less than £100 per annum are allocated by the Colston Research Society for medical research. A Beaverbrook Fellowship, tenable for three years, is open to all members of the university holding a medical qualification. University graduate scholarships are open to graduates of not more than one year's standing. The Michael Hiatt Baker Scholarship of the value of £200 per annum, open to a graduate from New Zealand, may be held in the medical faculty. The Markham Skerritt Memorial Prize is awarded every three years to that member of the university, not a member of the medical board, who, in the opinion of that board, has published the best original work during the three years. The Paul Bush Gold Medal is awarded in alternate years to the best resident medical officer at the Bristol Royal Infirmary.

Fees.—The fee for all the courses required for the medical curriculum, including hospital practice, is 205 guineas, paid by annual instalments.

Further information as to scholarships, courses, and fees can be obtained from the Dean of the Faculty of Medicine, or the Registrar of the University, Bristol.

UNIVERSITY OF DURHAM

The Medical School, King's College, Newcastle-upon-Tyne

(Formerly the University of Durham College of Medicine)

Under the recent statutes for the reconstitution of the University, the former University of Durham College of Medicine becomes the Medical School, King's College, in the neighbouring city of Newcastle-upon-Tyne, and constitutes the Medical School of the Faculty of Medicine of the University of Durham. Its classes and lectures are arranged to meet the requirements of the university in all the degrees granted by the university in the Faculty of Medicine, and also those of the other examining bodies. Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 700 beds, where there are facilities for the study of the various special subjects. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 90 beds, and has an annual indoor and outdoor attendance on 3,000 cases. In the Heath wing of the school itself there is a gymnasium and a set of rooms for the separate use of the students. The bacteriological department is housed at present in other buildings of King's College.

The Newcastle-upon-Tyne Dental Hospital and Sutherland Dental School is a component part of, and constitutes the dental department in, the Medical School. The dental hospital, erected within the grounds of the Royal Victoria Infirmary and equipped on the best modern lines, was opened in 1931, and it is possible to undertake here the whole of the dental curriculum (that is, systematic lectures, dental and general hospital practice, together with mechanical pupilage). The Dental Board of the United Kingdom recognizes the school for the purpose of granting its bursaries to students who are able to comply with the conditions laid down by the Board.

Postgraduate Instruction.—A comprehensive series of post-graduate courses are arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study afforded by the College, the Royal Victoria Infirmary, and other associated hospitals; and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer sessions, as well as an intensive course in the summer vacation. Courses of instruction are given for the B.Hy. and D.P.H.

Students' Union.—A Students' Union has been erected and furnished at a cost of over £54,000, and is in daily use. Separate accommodation (non-residential) is provided for men and women students.

Appointments.—Assistants in the pathological department, eye department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months. Resident appointments at the Infirmary are made every six months, and each year medical and surgical registrars (who also act as tutors) are appointed from candidates who have previously held resident appointments at any recognized hospital. These latter posts afford an excellent opportunity for postgraduate study, not only at the Infirmary, but also in the departments of anatomy, physiology, pathology, and bacteriology of the College.

Scholarships.—University of Durham Entrance Scholarship, £25 a year for four years; Pears Entrance Scholarship, £40 a year for three years (awarded every third year); Heath Entrance Scholarship (from Kepier Grammar School), £60 (renewable); Province of Durham Masonic (Entrance) Scholarship, £60 (renewable); Heath Scholarship for surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year.

The following scholarships are tenable for one year—namely: Tulloch Scholarship for elementary biology and organic chemistry, £20; Dickinson Scholarship for medicine, surgery, midwifery, and pathology, £20; Charlton Scholarship for medicine, £25; Gibb Scholarship for pathology, £28; Luke Armstrong Scholarship for B.Hy. and D.P.H. (Part I) examination in bacteriology, £25; Stephen Scott Scholarships for anatomy and physiology, two of £50 each; Philipson Scholarships for highest marks in Final M.B., B.S. examination, two of £45 each; Goyder Memorial Scholarship for clinical medicine and clinical surgery, interest on £325; Hamilton Drummond Memorial Scholarship, in aid of research in clinical surgery, about £50; Gibson Prize for midwifery and diseases of women and children, £10; Turnbull Prize and silver medal for surface anatomy; Outterson Wood Prize for psychological medicine, £10; Sewell Memorial Prize and silver medal for clinical pathology; Sir Thomas Oliver Prize and silver medal for the physiology of food and nutrition; and Ranken Lyle Prize and silver medal for clinical midwifery. Approved applicants may obtain special grants for surgical research from the Stephen Scott Research Fund and Heath Surgical Research Fund; for research in asthma,

etc., from the William Dodds Research Fund; and for research in dental science from the Parker Brewis Dental Research Scholarship Fund.

Fees.—The composition fee for lectures for medical students at the college is £132. Composition fee for hospital practice £46, plus £2 2s. yearly for three years, payable to the Committee of the Royal Victoria Infirmary. For dental students the composition fees amount to £236 for the B.D.S. and to £221 for the L.D.S., covering all systematic lectures and laboratory work at the College, general and dental hospital practice, and mechanical pupilage. Other information should be sought from the Dean, the Medical School, King's College, Northumberland Road, Newcastle-upon-Tyne.

Leeds

The School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The main buildings, opened in 1894, contain excellent dissecting rooms, well-arranged laboratories for physiology, lecture theatres, and classrooms. In addition, there is a well-equipped library and reading room and a museum of anatomy. The comfort of the students is secured by means of common rooms and a refectory. Extensions of the medical school buildings were opened in October, 1930, and the Algernon Firth Institute of Pathology in April, 1933. This last houses the Departments of Pathology and Bacteriology, and Experimental Pathology and Cancer Research, including the Charles Brotherton Pathological Museum. The General Infirmary has 628 beds, and includes ophthalmic and children's wards, a large out-patient department, and the Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge. The West Riding Mental Hospital at Wakefield is available for the study of mental diseases. Students also attend the practice of the Hospital for Women and the Leeds Maternity Hospital, and may attend also at the Leeds Public Dispensary.

Appointments.—Physicians' clerks and surgical dressers are appointed every six months; clerks in the children's department, orthopaedic dressers, ophthalmic and aural dressers, gynaecological ward clerks, maternity clerks, assistant physicians' clerk, dermatological clerks, assistant surgeons' dressers, dressers in the casualty rooms, junior and senior post-mortem clerks, laboratory assistants and dressers in the venereal clinic every three months. After graduation a considerable number of resident and other appointments become available in the Leeds General Infirmary, Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital, etc., occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

Scholarships.—The university awards annually on the results of the first examination a scholarship in the form of free admission to the lectures and classes given in the School of Medicine. The university also awards a scholarship on the results of the second examination, of the value of £68, in the form of free admission to the clinical teaching of the Infirmary.

Fees.—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £370, plus, of course, the expenses of living during the five and a half years covered by the curriculum. The composition fee for the course for the first, second, and third examinations, and for the clinical work at the Infirmary, is £242. The composition and clinical fee for those who have passed the second examination is £153.

Further information can be obtained from the Academic Sub-Dean or Clinical Sub-Dean, School of Medicine, Leeds.

Liverpool

The Medical Faculty is part of the university, and all the laboratories and other rooms are well equipped for the instruction of students proceeding to medical degrees and diplomas, and are situated close to one another. Clinical instruction is provided at the following hospitals: the Liverpool Royal Infirmary, the David Lewis Northern Hospital, the Liverpool Royal Southern Hospital, the Liverpool Stanley Hospital, the Royal Liverpool Children's Hospital, the Women's Hospital, the Liverpool Maternity Hospital, the Eye, Ear, and Throat Infirmary, St. Paul's Eye Hospital, and certain municipal hospitals.

Manchester

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains 586 beds, and has associated with it a large convalescent home (136 beds) and a Central Branch Hospital (5 beds). The courses in mental diseases are taken in the County Mental Hospitals at Prestwich and Macclesfield. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Clinical Work.—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well-known Hospitals for Children at Pendlebury and St. Mary's Hospitals for Women and Children, the Manchester Hospital for Diseases of the Ear, Monsall Fever Hospital, the Christie Cancer Hospital and Holt Radium Institute, the Hospital for Consumption and Diseases of the Throat and Chest, the Ancoats Hospital, the Salford Royal Hospital and the Hospital for Babies, all make arrangements for the instruction of students.
